While agreeing with the eminent pediatrician who said that "a rat isn't a baby and probably never will be," yet I would also point out that by properly planned and adequately controlled experiments we can learn much from rats which is applicable to the feeding of babies and grown people as well. And among the recent findings of nutrition experiments carried through successive generations of such laboratory animals the results of which are, I believe, directly and fully applicable to the problem of the attainment of the highest degree of human health, is the fact that starting with a diet already adequate, we may by improvement of the diet induce a higher degree of health and vigor. This has been strikingly shown in experiments with rats in which different families from the same stock have been kept for successive generations upon two different dietaries, the first diet adequate as shown by the fact that it has supported healthy growth, development and reproduction in some families for no less than six generations; the second diet differing from the first merely in that it contains a higher proportion of milk.

These experiments are still in progress, but certain results are already clear. Among the evidences of a higher degree of health which we find to result from increasing the proportion of milk in a diet already ade-

quate are the following: (1) More rapid growth; (2) more efficient growth, i. e., a greater gain in weight for each 1,000 calories of food consumed; (3) somewhat larger average size at all ages; (4) greater vigor as indicated by earlier maturity, larger capacity for reproduction, and greater success in rearing the young; (5) the period of full vigor was prolonged and the proportion of families dying without issue was greatly reduced; (6) the weight of

the mother was better maintained while suckling her young, and the young grew and developed better during the suckling period; (7) both infant mortality and the death rate after infancy were reduced, and this notwithstanding the fact that the females had borne and suckled more young.

There is no reason to doubt that all these findings, as thus stated in qualitative terms, will apply equally in human experience and that a high-

er degree of health will follow an improvement in the dietary of the individual or the food supply of the community, such as an increase in the proportion of milk, even where the original dietary was already adequate according to all current standards. Let us then seek to use our present knowledge to insure not only adequacy in the food supplies of all our people, but such food supplies and food habits as shall induce the highest degree of health and efficiency.

## Variations in Normal Physiological Functions\*

THERE is no better way of learning what disease does to an individual than by studying normal physiological changes in the individual. The daily cycle of life is composed of such changes. Osler used to divide the human race into the larks who wake up lively and interested, and the owls whose activities do not ripen until late hours. The variation of normals is an interesting study. The effect of food, of bowel movements, of the menstrual flow must be understood if the normal behavior of normal beings is to be understood. The celebrated story of the prevention of Voltaire's duel by the timely occurrence of a belated bowel movement might be employed to illustrate the interdependence of great worldly events and small individual happenings. Accepting these few generalizations as facts, physicians are often forced to ponder on the woeful ignorance of misguided half-truths which prevail regarding simple body functions, and it behooves us to try to analyze some of these popular misconceptions, in order to evaluate and separate truth.

Perhaps the most discussed phase of physiology in the world centers around bowel movements. There are men and women who honestly believe that if they do not have one or more daily evacuations of a definite size, specific consistency, and constant color, they are unable to perform their daily tasks to the best of their ability. On the contrary, there are perfectly healthy human animals whose bowels move any old time but whose brains and muscles, nevertheless, are constantly active and alive. Why the difference in these two individuals? The answer, we believe, is

partially physiological, partially psychological. The purpose and intent of the cleansing movement of the lower intestines is to rid the body of material for which it has no use. This material is composed in part of the "clinkers" left after food is burned, in part of bacteria, and in part of material secreted by the intestines. It represents the waste left over from the fire which induces and maintains the chemical reactions of the body. The reason why the reactions vary so much in individuals is apparent. No two individuals use food in exactly the same way, any more than do two furnaces burn coal in exactly the same way. One man eats food that has little indigestible residue and there are few "clinkers" or "ashes" left after the fire has burned; while in another person, a huge eater of coarse meats, vegetables or fruits, and other substances which the bodily fire cannot consume there will naturally be a large amount of material left in the intestines which must be eliminated.

Furthermore, even in two individuals whose food intake would be such as to result in the same amount of indigestible residue, the number and kind of intestinal movements would depend on other factors, such as exercise and habit. It is a well known fact that men accustomed to exercise who are plunged into a sedentary life usually, within a short period of time, become constipated. In such individuals the concurrent symptoms that occur, so often attributed to constipation, are probably due instead to the fundamental change in the man's life. For just as it is axiomatic to say that one gets out of any particular undertaking exactly what one puts into it, so it can be said that the intestines treat the individual in the

same manner as they are treated by him.

It is not as generally recognized as it should be that the real secret of intestinal hygiene is proper habit. If the correct habit is once started, if proper attention is paid in the beginning, then the movements of the bowels become, as they should, a normal automatic function. Start things right and it will no longer be necessary to pay attention to the intestines. It is a decided evil, which physicians see often enough in office practice, for individuals to center too much attention on their intestines. The psychological element should become as automatic as the physiological and, unless it does so, trouble is sure to follow.

### Factors of Sleep

In these days of the Freudian psycho-analysis so much that is bizarre, so much of the mysterious has been allowed to enter into and confuse the physiological factors of sleep, that it is almost like "angels fearing to tread" to venture to say that sleep is a normal physiological reaction required by normal individuals in the same way that food is required. What with discussions of the expression of libido during sleep, what with the wild interpretations of simple dreams, there has been produced in the minds of many people a feeling of wonder, even of fear, as to the nature of sleep.

Though we may not know what sleep is, we do know what it does. It rests the body, it rests the mind, and it gives the whole body mechanism, mental as well as physical, a chance to regain its power of "carrying on." There is nothing so necessary or so refreshing as sound sleep and there is no habit more difficult to

\*The sixth of a series of articles on "Popular Medical Misconceptions," beginning with the March issue of THE NATION'S HEALTH.

break, once the habit is formed, than the requirement of a given number of hours sleep to feel rested in the morning. The well known fact that one man needs only five hours sleep while his neighbor needs eight is a good illustration of the habit relation which cannot be separated from sleep.

Perhaps this idea of "habit" has been neglected even more in the discussions of sleeplessness. It is just as easy to form the habit of not going to sleep as it is to do the reverse. Physicians in practice frequently find, when the difficulty is analyzed, that the patients who cannot sleep simply have formed the habit of not going to sleep. Why they do this is hard to understand, but we believe there is a subconscious, constant thought in the individual's mind that he will not sleep, and this constantly recurring thought actually keeps him awake. If such a simple explanation is not the real one and the disturbance is much more profound, it is difficult to understand the very great therapeutic efficiency of a dose of bicarbonate of soda and the considerable assurance of its efficacy.

### Menses and Menopause

One of the most important results that have come from the removal of a false feeling of modesty which prevented women from instructing young girls regarding the care of their bodies, can be seen in the wider knowledge regarding the menstrual flow. Acceptance of this physiological function as a normal act, a realization of its variation in individuals, and the confidence that comes with knowledge have effected much in making the lives of girls less miserable.

Apparently, however, rational consideration is not so generally accorded that later period in a woman's life which is commonly known as the "change." This period is a normal physiological reaction also, though in some cases it borders closely on the pathological. The unfavorable reactions which occur at this period are frequently due to three causes, fear, ignorance, and resistance. Ignorance and fear can be removed usually by proper instruction, while resistance will likewise disappear if the thing is met as it arrives. As a rule the flushes, the headaches, the nervous symptoms are not serious and are only made worse by non-acceptance.

Just as men, accepting the onset of advancing years, must be contented with graying locks or, worse still, a

"shining dome," and get recompense in the thousand and one joys of life in which they could not participate during the period of youth, so women can accept things as they are and devote their energies to interests which will afford both recreation and diversion, and through which satisfying adjustments may be accomplished. The main business of life is to live. Whoever faces the facts of life with no denial—and without dodging—is in a fair way to get the best of life there

is. This is as true of the bodily mechanisms as it is of the psyche. If we are to establish those physiological automatizations which characterize healthful living, we must give just enough thought to the process to get the right habits going, and then forget we are burdened with bodies, for it may well be considered that notions of disease are as prevalent as organic disorders themselves, and that they always constitute a serious handicap.

## Call for Country Doctors

The problem of finding physicians for rural communities is a matter of growing concern. In the March, 1922 issue of *Health News* Commissioner Biggs succinctly describes the situation as it exists today in New York state, and touches upon some of the causes of the scarcity of doctors in country districts. In some parts of the state, particularly in the Adirondacks, there are no physicians within a radius of twenty-five or thirty miles. One logging community in the mountains recently lost its only doctor and within three weeks 250 of its 330 inhabitants were reported ill from influenza and other diseases, with only such medical attention as could be obtained from a busy physician in another village twenty miles away. Such instances of lack of medical care are by no means unusual. Within four years 92 rural towns and villages in New York state have asked the State Department of Health to help them secure physicians, and, although every effort has been made, the vacancies have been filled in only 62 cases.

All this has a direct bearing on the question of maternal and infant welfare which has been so widely and effectively agitated this winter. Although the New York Legislature rejected the Federal Sheppard-Towner Act, it has nevertheless appropriated \$130,000 for the development of new activities for the protection of maternity and child life. Yet, as Dr. Biggs points out, it is useless to talk about child welfare for those regions, at least, where there are no doctors, nurses or hospitals. A new task awaits the women whose indomitable energy was so large a factor in bringing about the adoption of the maternity bills. Their help is needed in the solution of the problem of rural medical service, for unless some solution is reached the new laws for the bene-

fit of mothers and babies will fail of their intended effect in large areas of the State.

The first thing to be done is to make country districts more attractive places in which to live, from the professional, social and economic points of view. In this direction President Pritchett in the latest report of the Carnegie Foundation urges that some of the professional advantages of city life be brought to the country physicians. Any moderate sized town, together with the surrounding area of open country of which it is the natural center, should be able to support a community hospital with laboratory, clinics, nurses, and consultation and diagnostic facilities as well as it supports a community high school. Even the small village can make a modest beginning with a little hospital which will greatly economize the time of the one or two local doctors. With the facilities offered by such hospital centers young graduates of our leading medical schools will be found more willing to settle in rural communities.

### The Veterans' Come-Back Club

The Come-Back Club, an organization of wounded World War Veterans who are studying at Columbia University opened at Bluefields, an estate at Blauvelt, N. Y., a camp which they will share with hundreds of other disabled soldiers in the schools and colleges of New York.

The Fire Waste Conference of the Chamber of Commerce of the United States met July 12, 1922 in Washington, D. C. At that time plans for a national fire prevention week were discussed, need for which was shown by the loss of \$1,300,000,000, in property last year from destruction by fire.

# Mansfield's Child Health Demonstration

## How a Typical American Community is Increasing Health of Next Generation

BY DR. WALTER BROWN, DIRECTOR, CHILD HEALTH DEMONSTRATION, MANSFIELD, OHIO.

THE Child Health Demonstration is a co-operative effort to show what a typical American community can do to increase the health and strength of its next generation. It is being conducted by the National Child Health Council, which is the pioneer organization for the co-ordination of the national voluntary organizations interested in the health of children. This Council is composed of representatives from the following organizations: The American Child Hygiene Association, American Red Cross, Child Health Organization, National Child Labor Committee, National Organization for Public Health Nursing, and the National Tuberculosis Association.

These organizations felt the need after long individual work in their own special fields of seeing their problems as a whole. For instance, the tuberculosis worker soon found that his problem was not one of tuberculosis alone, but was interrelated with problems of the worker interested in child labor. Or again, the American Child Hygiene Association found that if it wanted to be of real service it must take into consideration the family as a whole, not only the baby. In other words, these organizations had come to the realization that their work was not only interrelated, but also inseparable. Out of this realization grew the National Child Health Council.

Although coordination in the national child health field is almost a pioneer effort, the Council has made remarkable progress. The member organizations clear their literature, plans, and itineraries through the Council. Methods of coordinating their work with other national organizations, public departments, and state and local agencies are being developed through reports, conferences, and field experimentation. National advisory committees dealing with such subjects as foods and nutrition, health education of school children, current child health news and literature, health provisions for state laws relating to chil-

dren, and so on, have been organized. These committees consist of representatives of national bodies which have expert knowledge and experience to contribute and of individuals with outstanding ability. Their chief function will be to collect, study, and make available to the entire country the best information and the most authoritative opinion on subjects that contribute to healthful childhood. These advisory committees have already contributed much to the Demonstration.

One of the interesting features of the Demonstration will be "team work" between the public departments and private agencies in the city and county, on the one hand, and the six national organizations making up the Council, on the other. Very early in the life of the Council it became apparent that something more than conferences and committees were necessary successfully to coordinate their work. It is believed that a well planned cooperative demonstration in a typical American community would do more than any one thing to bring about the desired result. A sum of \$200,000 supplemented by funds from the local community has been set aside to carry on this demonstration for a period of five years.

The Council has made long and careful study of the relative merits of approximately eighty communities

which applied for the demonstration. Mansfield and Richland County won its vote because they most nearly met the requirements. The chief purpose was to select a city and county which would be fairly typical of the average of American life, the city to have a population of between 20,000 and 30,000, and the rural area surrounding it an equal number. Some of the specific conditions laid down were that a normal percentage of the population should be engaged in manufacturing; there should not be any strikingly predominant racial stocks; there should be a variety of industries; the surrounding area should be an agricultural territory; the community should be located in the Birth Registration Area, and vital statistics should be fairly complete; the mortality of infants and children should be strikingly abnormal.

In meeting these requirements Mansfield and Richland County have shown a deep sense of responsibility to the entire country for the success of the experiment, in addition to the natural interest and pride in the development of local resources. The judgment of the Council in selecting Mansfield and Richland County as the place for the demonstration has been amply justified by further study.

The City of Mansfield is a hustling,

Nurses corps ready to leave Child Health Demonstration headquarters to cover the entire county.

\*Read before the Forty-Ninth Annual Meeting of the National Conference of Social Work, Providence, R. I., June 22-29, 1922.

Every school child in Mansfield and Richland County, Ohio, a community of approximately sixty thousand, is being examined in a cooperative demonstration in an effort to improve the health of the younger generation.

wide-awake industrial center with a great diversity of manufacturers. Its population of 31,000 contains no great predominance of any one racial stock. The age distribution of its population meets the statistical requirements of the demonstration. The social, educational, and commercial organizations are of a character and quality which promise to be of great value in our work for the health of the child. There is a good average group of physicians who are interested and willing to assist the demonstration.

Richland County is a typical agricultural region in the center of the Ohio wheat belt. It has a population of about 28,000 with a number of villages, and one small city of five thousand inhabitants. The school system is well administered. Practically no health work is being done by the official agencies. The Farm Bureau and the Red Cross are the two most important organizations.

The objectives of the Demonstration may be briefly summarized as follows:

(1) To work out a practical plan and an economical method whereby the resources of these national organizations can be effectively delivered to the local community, this to be done through and with the local agencies.

(2) To assess at their true value the various procedures now being advocated for the improvement of the health of children.

(3) To combine the best of these procedures in a way calculated to induce the local community to recognize their value and to make them a permanent part of their community life.

(4) To make available the training facilities for preparing workers to conduct this type of health work.

The courses of training are to be made a part of the instruction in the various types of schools from which the community draws its trained service.

(5) To demonstrate how any similar American community can, by the adoption of these methods, promote the health of its children. The attainment of these objectives will depend upon several conditions. A method for securing real approval and active participation of the community in the projects of the demonstration. A way to overcome the natural reaction of any community to suggestions and directions from the outside. And a consistent refusal to duplicate already established health activities.

The Child Health Council is convinced that the final success of the Demonstration will hinge upon it being properly related to the official and voluntary health agencies now at work in the community. Consequently, a wide latitude of local administration has been provided for. The Council stands in an advisory capacity and functions in the Richland County solely through the Director. This has made possible the establishment of local machinery for local approval of and participation in the projects of the Demonstration.

#### Local Advisory Council

One of the first steps was the organization of a local Advisory Council. This Council is composed of a representative from each of the official health and educational departments, the social and welfare agencies, medical and dental societies, industrial and labor organizations, religious and civic bodies, and the agricultural groups. This Council has elected its own officers and a small

executive committee which acts constantly with the Director in working out the details of local administration. Through this Council, the community has begun to assume its share of the responsibility for the Demonstration. It has secured and is equipping headquarters which will be used for the administration offices and for the main health center.

Any well rounded program for the promotion of child health requires the support and cooperation of the following recognized groups: (a) health authorities (city, county, and state); (b) educational authorities; (c) medical profession; (d) dental profession; and (e) related social and health agencies.

This is being accomplished for the Demonstration through the Council and its committees. The staff of the Demonstration consists of a small corps of trained workers. It includes a director for each one of the special services—medical, nursing, health education, nutrition, and social service. Each one of these individuals will strive to develop additional personnel out of local resources. Our energies so far have been directed along three fundamental lines which it is believed are a necessary foundation for further work: namely, (a) study of the health needs and resources of the community; (b) methods for securing adequate medical and nursing care for children; (c) methods for providing for proper health education.

A careful and systematic study has been made of the vital records of Mansfield and Richland County. To add to our accurate knowledge of sickness among children, we have just completed a Health Census. At the same time, we are recording the social and sanitary facts that will furnish an accurate picture of the health conditions of the community. From a study of these materials we will be able to gauge the health needs and estimate the health resources available for children.

The plans of the Demonstration include a primary Health Center at Mansfield with secondary centers in various parts of the county. From these centers as headquarters it is hoped to work out methods for continuous health supervision from prenatal through the adolescent period. The medical service will be in charge of a full time, well trained pediatrician, who also will be available for consultation service to the local physicians after the plan so successfully worked out at Framingham. Through

these centers the contributions of the nursing, health education and nutrition services will be co-related for the benefit of the health of the individual child.

The reaction of the community to the methods being applied can be best illustrated by a brief description of some definite projects. It was decided to offer to conduct health examinations for the children of the third and fifth grades. The purpose was three-fold: to test the functioning of the local Advisory Council; to demonstrate to parents and the professional groups the character and value of the examinations; and to secure experience and data on which to base a permanent system. The project was presented to the Advisory Council. Through the representatives of the medical and dental professions, the approval and participation of these groups were secured. The consent of the educational authorities was procured. The Parent-Teachers Association gave assurance of active cooperation.

This is the way it worked out. A health examination corps was organized. It consisted of a physician, a dentist, a nurse, a teacher, and two volunteers. A letter was sent to the parents of each child through the school teachers. This letter described the purpose and extent of the examination and urged the parent to be present. If that was impossible and the examination was desired, the parent was asked to sign a consent slip which had been enclosed.

#### Examination Routine

On an appointed day the examining corps visited the school. The volunteers who had been appointed by the Parent-Teachers Association performed the clerical work. The nurse made the tests of hearing and weight, and the preliminary examinations of the throat and for posture. The teachers weighed and measured the child and noted the normal weight. The dentist made a careful examination of the mouth. All children accompanied by parents, or having signed slips, were then passed on to the physician for the more complete physical examination.

The response was more than gratifying. Out of 1,119 children examined, 718, or 64.1 per cent, had the complete examination. Out of this number 15.4 per cent were accompanied by one of their parents. The experience gained by these examinations is now being discussed with all of the groups. It seems certain that our

Physicians and dentists who voluntarily assisted in the first health examination in Mansfield.

first project has attained its three-fold objective.

One of the prime needs for successful child health work is a unified, economical, and practical public health nursing service. We are attempting to secure this by a real co-ordination of the existing nursing organizations. It is not planned to establish a separate nursing corps for the Demonstration. The intensive work for children will be carried on by adding personnel to the local nursing groups. To the end that the program shall be unified, these groups have elected the Director of Nursing of the Demonstration as their head. In addition the Main Health Center will become the headquarters for all the nurses. This will make it possible for the individual association to maintain its identity while we are developing the kind of nursing program which will best serve the whole country.

A large percentage of the ill health among our population is due to family habits. The best way to attack this problem is by means of health education. The best place to start this attack is by introducing proper courses of training in health habits into our schools. This is one of the major projects of the Demonstration. Fortunately we have been able to secure the hearty support of the local educational authorities. They have appointed the Director of Health Education of the Demonstration to the same official position in the schools. This will enable us to pro-

vide the content of health courses; to assist in training the present teacher to teach these courses, and to stimulate the normal schools to include such training in their courses for future teachers. In other words, we have set up the machinery which will make it possible to deliver the accumulated experience of our health educators to the local community.

The above description covers the origin, policies, and preliminary steps which have been taken to place the Demonstration on a sound working basis. It is planned gradually to add to the program the contributions of the mental and social hygiene groups. At the same time we are endeavoring to play our part in the development of the co-related social agencies of the community. While it is too early to speak of definite results, we have every reason to be hopeful that out of the Demonstration will come ways and means whereby the resources of the entire health field can be successfully delivered to the local community.

The Institute of Applied Pestology recently organized in London, states its object thus: To wage war by all possible means on vermin and all pests inimical to man's welfare, and to enlist the help of scientists, medical officers of health, sanitary officers, manufacturers, chemists, and others, and the public generally, in the cause of hygiene, well-being, and self-preservation of humanity; and to endeavor to coordinate the work of these to this purpose.

# The Foot Factor in the Future of Women

## Shoes Conforming to Foot Shape Add To Feminine Efficiency and Comfort

By HARRIET WILDE, NEW YORK CITY.

WHAT have feet to do with the future of women and what does the future hold for women? Whatever it holds will be influenced by the feet of women, for feet have to do with almost everything in life and ultimately with the success or failure in terms of which the future will be spelled for each one.

Feet are even more fundamental than they seem. They are veritable foundations, and no superstructure can prosper unless based upon foundations suitably planned and strongly built. A Woolworth building with wobbly foundations would not long persist to gladden the eyes of the commuters into New York. The whole is no better than its underpinnings. The individual is no better than the feet she stands upon, the family than the feet of the family, the group than the feet of the group, the state than the feet of the state, and so we might go on until we traced the destiny of nations and of international relations. Feet as foundations have a very direct effect upon health, and health bears a direct relation to personality and success. The success of the race, therefore, depends in a measure upon the feet of the individual women of the race.

Feet are not only fundamental—they are universal. Everyone has feet. Everyone starts life with an equal number and about an equal amount. Except in cases of disaster the number remains constant through life though the amount may vary considerably later. And the plan is good. The mechanism is perfectly adapted to its purpose of weight bearing and locomotion.

Feet are meant for use. In walking, running and dancing; they take us to work and to play; they are with us as good friends and companions all along the road even unto the end. If they are thus to be useful members of the body politic it is necessary that they be strong, that they shall endure. The normal foot is a strong foot. It is also intended that they shall be comfortable. Nothing that is uncomfortable can be useful long. Comfort does not necessarily mean degeneration. It means freedom from

*In this day of misshapen feet it is necessary to go back to the foot of the baby to gain a clear picture of the beauty and mechanics of the foot. When one considers that feet are among the most useful and continually worked members of the body and that from their misuse result fatigue and various bodily aches not to mention the injury to the feet themselves, it is imperative that shoes be chosen for the shape of the foot rather than the foot cramped into shoes of fashion's dictates.*

*High heels and pointed toes must certainly give way to a shoe following the lines of the foot before the women of America can expect to obtain foot comfort and efficiency.*

limitations and restriction with ability to function. The normal foot is a comfortable foot.

It is further intended that feet shall be beautiful. They are beautiful to start with as witness the bare foot of a baby. Its characteristics are these:

The long straight toe has an important part in the walking step.

Narrow at the heel, broad across the toes, like a triangle with its base in front and pointing backward; straight on the inner border, so that its big toe and heel and the line connecting the two would fit along a ruler or the edge of the table. Of its five toes, the big one lies flat and points straight forward, while the four little ones curve and rest on the rounded surface of the last segment. When two of these little feet are placed side by side the inner borders and the big toes touch each other, and the longest part of either foot is at the end of the big toe. If we look at our hands we find them long on the middle finger with the other fingers sloping toward the middle finger. The hand is primarily intended for grasping and for fine adjustments, bringing the fingers together—thus the middle finger needs to be longer than the others. The foot, on the contrary, bears the weight of the body as it goes forward and the long straight toe has an important part in the walking step.

Feet are small in proportion to the structure which they support, but they are so built that they carry the superincumbent weight easily through their arches as the weight of a bridge or building is carried through its arches. The two main arches of the foot are the longitudinal arch curving under the foot from heel forward to ball and the short arch which lies at right angles to the long arch across the front of the foot at the base of the toes. This is known by several names: anterior, transverse, or metatarsal arch. Through the strength and elasticity of the ligaments and muscles the bones of the foot are held in place and the function of the arches in supporting the foot is maintained.

To go back to the baby, as we watch him grow changes take place in his hands. They become larger, heavier, stronger, acquire lines of character, develop greater usefulness than the baby hands, and yet remain comfortable. They vary in type: some are slender and delicate, some broad and stubby, some acquire great deftness in different directions, but

their essential characteristics are the same as they were in the hands of the one year old.

Is it the same with feet? Are they the same shape? Are they just as strong, as comfortable, and as beautiful? A few exceptional ones possibly are, but the majority are not. In adult and middle life are they strong? If so, why are so many firms selling supporters and braces and arch preserving devices, and why are so many special kind of corrective appliances on the market? If feet are comfortable, why are so many chiropodists getting rich, why so many women shifting from one foot to another when they have to stand, sitting down at the first opportunity and riding short distances when they might swing gaily along getting a bit of exercise and saving their nickel?

### Feet Can Be Beautiful

One continues to smile at the idea of beauty in the adult foot. But if faces and hands remain or grow beautiful, why should not feet? Characteristics of the average grown up foot are fatigue and dull or acute pain; unsightly and uncomfortable corns and calluses, pinched and overlapping toes which, instead of enjoying space each for its own activity and independence, lie all crowded together like too many persons in an unregulated tenement. The big toe that once led the march is pushed over toward the center either under its neighbor or on top of it, losing its leverage ability entirely and causing an ugly and often very painful big joint to develop at its base; and arches instead of curving upward proudly lie humbled and most probably objecting loudly.

In addition these local difficulties often result in fatigue and weariness, leg ache, back ache, head ache, poor posture, indigestion, constipation, with a host of accompanying conditions; pelvic disorders, menstrual irregularities, inability to exercise sufficiently with resultant overweight, irritability, ill-health, inefficiency, unhappiness.

Leaving out accident and disease conditions, such as infantile paralysis and bone tuberculosis, two principle causes have brought the lovely free feet of the child to this state of unhappy slavery: first, the way we use our feet, and second, the garments we clothe them with; how we walk and what we wear, or what we do with them, and what we do to them. The feet themselves are blameless. They were perfectly planned and gener-

Y. W. C. A.

The short arch which lies at right angles to the long arch across the front of the foot at the base of the toes has for its purpose, in conjunction with the longitudinal arch, the support of the foot.

ously provided. It is we ourselves who are at fault; sometimes through ignorance, sometimes through carelessness, sometimes apparently when we know better, with direct intent to kill. Of the two causes one is almost as bad as the other, though more attention has been paid to one than the other. Within the last few years there has been considerable agitation for suitable shoes, but comparatively little has yet been said or done about the use of the feet even by people one would expect to find the most intelligent on the subject, i.e., the directors of physical education.

How then should we use our feet? Again we go back to the nursery. A normal baby, if left to her own devices unassisted by over-ambitious parents or nurse will approach the walking and standing problem in this manner. Lying on her back she kicks lustily and waves her arms, lying on her abdomen she does the same. Next she rolls over from her back to her side and from her side to her abdomen, then she rolls back. Next, lying face down and kicking she begins to move, hitching forward or back her whole length, except her head, in contact with the floor. It may be that she shoves along on her back first, anyway she begins to progress, sometimes even sideways like a crab. All this time she is strengthening muscles of legs and back, abdomen, chest and arms, until she is creeping on knees and arms, the forearm resting on the floor. Next she is up on her hands and knees, then hands and feet. Along in here somewhere she has found strength enough in her little trunk to sit upright, so she creeps to the wall and sits beside it. Then she takes hold of the wall and pulls herself to her feet

—drops down and scampers away on all fours to another pulling-up post, and so on for several months cruising about the house sometimes even up and down stairs before she can walk. Then one proud day she stands up, casts off support and runs triumphantly half way across the room. Pretty soon the run slows down to a walk, and how is she walking? This, remember, is the *normal* baby, properly fed, with parents above the average who have watched her follow her own instincts, and develop her weight bearing muscles. She walks at first with feet wide apart and toeing in, her big toe lying flat on the floor, her toes gripping and her two main arches developing as they are put into use. (I am also supposing that she begins to walk bare footed, or in the softest of kid or chamois moccasins.) As her legs strengthen they come closer together until they are straight. Her feet point straight forward, big toe leading, aiming in the direction she is planning to go. And straight forward they will stay as long as she is let alone. Thus the normal baby stands and walks, thus the American Indian walked, thus all foot prints of primitive peoples are shown in all anthropologies, thus the baby girl of today should grow into the woman of the future, advancing straight-footed toward any goal.

### Clever Mechanism of Foot

Standing with feet parallel the weight is borne easily through the longitudinal arch of the foot, which so long as it comes down directly from above will carry it easily, as will the arch in a building carry the weight of the building. Suppose that building were set sideways over its arch, what would happen to the arch? What happens when we stand and walk with toes pointing outward? This happens: The weight hits the arch of the foot on the slant and swings it in toward the other foot and down toward the floor, bearing down on muscles and ligaments, making them work at a tremendous disadvantage; tiring, straining, and treating them as they were never meant to be treated. Muscles are something like elastic bands, when stretched out they tend to return, but if repeatedly overstretched they lose their returning power and are not in condition to respond to stimulus. Standing with the toes turned out brings the weight down upon the arch in the same wrong direction and in addition puts pressure upon the big toe joint and destroys the pushing,

X-ray of woman's foot in high heel showing weight thrown forward on the anterior arch.

lifting and gripping properties of all the toes. In toeing out we are not using our feet, we are taking them with us on the end of our legs. They are just about as useful as rubber tips on the end of crutches, they come between us and the floor. With lack of use of the feet, deterioration, loss of tone, and softening occurs. The foot muscles thus treated cease to support the arches, which are the secret of the successful foot, and down they go resulting in flat foot, calluses, fatigue and pain.

Sometimes the arches go quite early in life, sometimes not until later. Some people seem to escape all result of wrong doing. These people are really menaces to society. They lead others astray by their example and all of those others may not escape as they did. Other things help the wrong use as too much weight above, out of proportion to the size of the feet. In this respect light weighters get off more easily than their heavier friends. Too much standing especially when standing in the wrong way often causes foot trouble. Saleswomen, laundresses, machine operators, nurses and teachers who stand to teach often suffer from weak feet. Standing is worse than walking, for most people walk straighter than they stand, and there is a minimum activity in walking even in the wrong position.

With the coming into vogue of foot covering, much trouble and in recent years much controversy has resulted. The arguments for some type of foot clothing are undeniable, however radical we may be—inequalities of temperature, inequalities of pavements and floors, stones, tacks, dirt, convention, appearance, habit, and

the many, many people whose living depends upon the shoe and stocking and allied industries. Is it not essential therefore that the coverings for these very useful parts of our machine be as rational as possible? Shall they not increase their efficiency, assist in strengthening them, allow them to remain comfortable, permit their freedom, enhance their beauty, and encourage their normal use in the normal position?

Speaking of hands once more, we cover hands for cold, for convention, for appearance, to increase their strength and power for some activities, such as farming, and handling rough or heavy material, but we cover hands with garments which correspond to their shape and use. Our hands are quite useful with gloves on. If we are going to sit with them idle in our lap and listen or look for an evening, we wear thin, small gloves, but if we are carrying a suitcase or driving a car we wear loose, heavy ones. Whichever they are, they are made in the likeness of our hands.

#### What Shoe Does to Foot

It would seem that our hard working feet should receive the same consideration; their covering should be the shape and size of the foot. The foot originally was narrow at the heel and broad across the toes, apex of the triangle at the rear. Where is the apex of the triangle in most of the shoes of today? It was straight on the inner border, the great toes of the two feet lying close together. What about the pie-shaped piece that could be fitted in between most of the toes of the conventional shoes? Its longest point was at the end of the great toe on the inner border. Where

is the longest point of most shoes? Is it not in the middle more like fingers of a glove? The longest point of the glove should be in the middle because the middle finger is the longest finger, but the shoe should not be long in the center, because the longest point of the normal foot is not in the center, but on the inner edge, at the end of the great toe. It is hard to believe this when we see on all sides and in most shop windows shoes for men and women pointing long in the center. Convention and custom have trained our eyes to see so-called beauty in a shoe of this shape. Boats must be pointed to make speed by cutting through the water, but even in New York the congestion has not yet reached the mark where we must plow our way through the crowd with our shoes. Even so-called sensible shoes, English Brogue and the "flapper" sandal of 1922, although round on the end are still long in the wrong place. It is custom and fashion after all. It is also hard to believe if we could look at rows of adult feet. If two dozen women at any club meeting stood barefooted on the platform, how many of the feet would have straight great toes, free and uncrowded little toes full of activity and strength? They were all so once. Some began in childhood to go astray because they grew rapidly and unwittingly were kept in short stockings and short shoes. The very first harm may be done by the wool booties of infants which shrink in washing. Some never had shoes or stockings too short, but as soon as they outgrew children's sizes were put into adult shoes pointing in the center, long probably, but curving in at the base of the great toe, pushing it over and crowding the little toes and the trouble began. Nowadays children are often put into adult shoes at seven years old.

Very much less need be said about heels since the fashion swing is for lower and lower ones. The latest fad shoe one sees on the feet of girls is almost heel-less. But because it is so recently that heels were high, and because fashion is bound to change again before long, it is well, briefly, to consider heels. In the first place, why heels at all? Teeth arrive when we need them, nails protect the tips of our fingers and toes. Eyebrows and eyelashes guard the delicacy of eyes, and yet people feel that somehow in the process of evolution the finishing touch was forgotten in the supporting point of the whole structure.

The origin of high heels is interest-

ing. As the bottom of the shoe wore out first on the heel end, that part of the shoe was made thicker so that it would last longer, merely an expediency measure. The first high heel was worn by a short French king, a man, to increase his height, a vanity measure. We would consider high heels on men very silly now, but they are no sillier than the pointed shoes men have recently been wearing. The elevator man in our office building looked so miserable one clear, crisp morning last winter that I asked him if he were ill. "No Miss," he said, "but I have such sensitive feet, this cold weather certainly does make them cry aloud." His feet were crying aloud against the pointed shoes quite as much as against the weather.

### The Argument for Heels

If we must wear heels as custom, tradition and trade seem to think we must, the lower they are the better. People will tell you that they never wear high heels, they always wear Cuban heels, measuring in some cases two inches or two and a half. An inch is the maximum height allowable for the normal foot. In this the foot is almost as useful and active, as without. People will also tell you that they have such high arches they cannot wear low heels, with a little self-conscious belief that there is an added aristocracy in this inability, a strain of good old Southern or Knickerbocker ancestry. The truth is that a too high and rigid arch is almost a deformity, and the discomfort of the low heel is caused by a condition quite off the normal.

High heels may cause all sorts of troubles: short calf muscles at the back of the leg, with pain in the leg and back. When the weight is thrown forward, instead of sailing on an even keel we are down at the head, or down on the anterior arch, which under a greater proportion of the weight than it is intended to carry protests and flattens. Pushing flat against the unyielding surface of the floor or pavement it develops a callus on the under surface in the center. Discomfort, fatigue, and pain result, pain sometimes on the sole of the foot, sometimes through rubbing in relaxed joints or pinching of nerves in the toes and top of the foot, even way up the leg. Then if at the same time that we tip forward on to our toes we crowd them into a space quite different in shape from their shape, we turn these already maltreated toes out and bring the pressure all side-

ways, and sometimes in addition to that we weigh several pounds more than we should.

The shank is the under surface of the shoe connecting the heel and toe. In other words, it is the covering of the long arch part of the foot, the arch of the shoe. For generations this shank has been made with a steel insert. Many shoemakers will tell you that steel is necessary to hold up the shoe, that without it the arch will break down. This has been proven false by the firms who are now selling shoes made with no steels in the shanks. These are flexible shank shoes which are increasing in number, as the advertising pages of the newspapers show. (To test flexibility, bend the shoe down in the middle, bringing the toe and heel together—not as people often demonstrate by bending the shoe up at the ball.) When the shank is flexible the foot is able to exercise its muscles in walking, and as muscles are exercised they grow stronger. Walking with a flexible shank and walking straight with a flexible shank will make feet stronger and stronger. It is also easier to walk straight with a flexible shank, because the shoe can bend in the center as the foot bends, and not have to turn out because of the stiff shoe. It encourages the gripping qualities of the arch and the toe muscles.

For this same "freedom" reason, low shoes are better for the feet than high shoes. Is it logical to bind and tie up tight a group of muscles that we want to strengthen? Low shoes, mocassins, sandals, barefeet,—the less restriction the better. Many women have recently been indulging in the joy of barefoot dancing, rhythmic. At first the feet were tired and sore from the unaccustomed use. They felt as other parts of the body have felt after a first game of tennis or a horse-back ride.

### Sense Not Fashion Dictator

And now what can be done about styles? Follow fashion markers, passively do what a few style setters, mostly men, say? Once upon a time an English king suffered from gout and had to have his shoes built wide and square at the toes. Fashion followed its king, and shoes for men and women were made square and wide. Shall we follow fashion like sheep, or shall we rise up in our independence and lead? Can we not educate to keep feet good: first—through nutrition, as the world is fed so will it grow and walk; second—through

Flat foot can be diagnosed almost without further examination from the appearance of this shoe.

right habits of using feet, standing and walking. Here the main responsibility might seem to rest with mothers, nurses, physical educators. But it does not end there. Every one is a daily example to hundreds of others. Every well dressed woman walking straight footed and free footed helps another woman or girl to become the same. Demonstration holds an important part in all education. The United States Army still toes out. When the men's feet broke down during the war they were turned forward and given foot exercises, but they were first encouraged to break down by long hours of standing and walking in a bad position. The New York City Police force on the contrary is taught to toe forward, and much emphasis is laid on foot care. The pamphlet "Ailments of the Feet, Their Cause and Prevention" was written especially for the men on the force; for no patrolman or traffic regulator is more efficient than his feet. Think of entrusting the safety of our citizens to men made irritable and ineffective by troublesome feet! Third: educate by wearing and talking good shoes. Every well dressed, normally shod woman helps some other woman or girl to wear the right kind of a shoe. Often you will hear some one say "I never have any trouble with my feet, why should I wear such looking shoes?" A little while ago I used the word "menace." These are the "menaces,"—women who in spite of going contrary to all the foot laws apparently suffer no consequences. This happens in other lines than feet—digestion, eyes, etc., but sometimes the individual suffers later. No pair of feet can live to

themselves alone; they have an influence, a radiation, and it will either be for good or for bad. So you see it is not all in the hands of the mothers, teachers, and physical directors.

While this educational effort and example will doubtless produce a future of perfect feet, in the mean time there are all around us pathetic members that are not joys to own, that are suffering the results—of all sorts of things. For those I would like to make a few suggestions. Don't put up with them, patiently or impatiently! Get rid of them! Not the feet as wholes but the causes of the discomforts. Find out what is wrong with them, and tackle one problem after another. Get them as

good as you can. It may take time, it may cost money and trouble, even operation in some cases, but it will be worth it, and remember it is seldom all the fault of the shoes. People say "I have spent hundreds of dollars on shoes and nothing has helped me." There are almost no feet that can't be helped, many that can be cured. If the trouble is short calf muscles, they can be lengthened; weak arches can be strengthened by exercise; big joints can be straightened; calluses and corns can be removed; habits of walking can be changed.

But don't make the mistake of following the advice of someone who sees your foot—not even "Through a glass

darkly"—but through a stocking, not at all. Many women will accept as scientific data what a shoe salesman, a so-called "specialist," tells them, forgetting that the shoe salesman's chief interest is not always in the "future of women," but in the selling of shoes. There are happily an increasing number of men in the shoe business who are as honestly interested in the welfare of feet as they are in the cash transactions in their stores. A few pioneers struggled along for years trying to do for women's feet in spite of the women themselves. What can they not do when the women are on the same side demanding the right shoe? Increasingly right standards are coming to the fore.

## Heart Disease and How to Prevent It

### High and Increasing Cardiac Mortality Makes Disease Public Health Menace

By ROBERT H. HALSEY, M.D., NEW YORK CITY.

SINCE 1916 an increasing amount of attention has been directed to the study of disease of the heart. The more careful the detailed study has been, the greater the impression made that heart disease has become a very important, and is becoming the foremost, item in public health consideration. As yet the evidence has been obtained from only three sources in any detail and from no one completely. The evidence demonstrating the national importance of the problem is the increased death rate in the general registration area; thus in somewhat over half the states of the Union, representing approximately 60 per cent of the population, there was, for the year 1920, an increase in the rate from 131 to 141.9 per 100,000. This represents approximately 10,000 more deaths from this cause (during the year. During the same period (1920) the deaths in the city of New York increased by 912, from 10,433 to 11,345, in a population of 6,141,446. That this increase is not restricted to New York is shown by the increased rate of 144 in Detroit, a city with a population of 993,678, and having much better general health conditions.

In the *Statistical Bulletin* of the Metropolitan Life Insurance Company for April, 1922, page 4, one reads: "By March (1921) the rate for organic heart disease had reached 168.2 per 100,000, one of the highest figures

ever recorded in any one month among Metropolitan Industrial policy holders."

Turning now to the examination of the living, one finds that of the men between the ages of 18 and 30 years in the draft during the recent war 468 per thousand were found to have noteworthy physical defects and 35 per cent, or 1,000,000 men, were rejected as incapacitated thereby. Most remarkable is the finding that 13 per cent, or 130,000 men, of the 1,000,000, were incapacitated by cardio-vascular defects. When one considers that the draft reached only a twelve-year section of the male population, one is left to speculate what the remainder of the male and of all the female population, which is totally unaccounted for, would show.

The next large group of the population which has been examined is the public school children between the age of six and sixteen. In general, the surveys indicate surely that 1 per cent have organic disease and one-half of this figure have very serious damage. And, since a very large proportion of the children having heart disease are found to have it when first entering school, there is no doubt but that a large group of children during the pre-school age have suffered the damage from heart disease.

Not only does heart disease shorten life, but it incapacitates the individual for full productive achievement.

There is, because of it, a direct loss of earning power, which can be readily estimated, to be added to the economic loss of the community.

According to the insurance statistics, there is a curtailment of twenty-four months in the life expectancy of females and twenty months in that of males. The loss is heavier among the white than among the colored. It is indicative of what may be accomplished by proper preventive measures that the mortality among the colored race is falling. Something of the great cost to the community of heart disease may be realized by the study of the admissions to one of the large New York hospitals. In one year, 159 patients with heart disease were admitted, costing 3,207 hospital days, or, at the prevailing rate, \$15,714. That is, each case required an average of twenty days or approximately \$100. Add to this wages lost of \$100 as an average, gives the figure of \$200 for each person with heart disease. From figures reported by the Association Cardiac Clinics, there are over 4,000 patients attending, thus there is a potential loss of \$8,000,000 in the cardiac clinic patients of New York. The deaths, for the country as a whole, from heart disease approximate or exceed 150,000 each year. On the above basis of \$200 for each patient, there is a yearly loss of \$30,000,000 as a minimum.

If we recapitulate we find that the deaths recorded in the country at large, in the cities and among holders of life policies, show an increasing rate from heart disease. The male population between eighteen and thirty years of age shows a large number handicapped by heart disease. The young school group, six to sixteen, shows at least 1 per cent so damaged. From all these sources the evidence is such as to justify the assumption that a large and appreciably increasing proportion of our population suffers and dies because of heart disease.

Such being the case, it behooves us all to devote every energy to such measures, which will not only prevent a further increase, but will bring about a reduction in the number so handicapped.

### Annual Death Toll 150,000

Any disease which involves so many of our population that it has a death toll of 150,000 each year may well be considered a public health problem, a problem of a magnitude which requires and justifies the most careful and accurate study in order to discover and outline intelligently the methods by which it may be prevented. Before practical solutions can be devised, the various phases of the problem must be investigated, and this can only be done by gathering information from all sources and of every kind having a bearing upon the subject. From data thus collected the origin and course of the disease may be learned as well as the effect of certain procedures of a medical and surgical nature. As fast as facts are available they should be disseminated among the profession and to the public in order that both may learn the way to accomplish prevention and, in the learning, become imbued with an enthusiastic will to prevent. Recent advances in public health work have indicated the presence in the public of the power and desire to carry out any plan if it is clear and effective. No plan can be effective unless it provides for the intelligent cooperation of the various public health agencies and the public.

From each individual victim must be obtained the facts about the conditions of life, environment, the story of the onset and course of the difficulty. At the same time, a careful physicial examination must be made, and later repeated, in order to learn the type, degree and changes in the condition of the heart. Every one found to have a damaged organ must

be classified and differentiated, so that the advice shall be personal and show discrimination, not only in the method of life advised, but, also, in the application of knowledge gained, so as not to spread the disease to others; for, as surely as there is an increase in the incidence, there must be definite ways in which that incidence can be decreased.

Of course, the above requires frequent physical examination of those who have a damaged heart. Repeated examination with this purpose in view will emphasize the need of, and create a demand for, periodic examinations, whether the person be well or ill. The employer will learn the importance of knowing the condition of his workmen in order that they may not be permitted to do work which will ultimately incapacitate them. The employee will learn to understand the importance of knowing his condition and what work it may be possible for him to do without injury to himself.

Periodic examinations will not only reveal the often unsuspected damaged organ, but will provide the opportunity for conference and advice, as to what habits or conditions of life might well be altered to prevent the actual injury by overtaxing the already damaged heart. Periodic examinations will be valuable, too, to determine the actual morbidity of the damaged heart.

A survey on a broad scale and from various points of view should reveal what elements of climate or housing make the occurrence of heart disease more frequent in one country than in another; or in one part of a country than in another part. Thus, it may be possible to determine what can be done to diminish the incidence of rheumatism in England or the occurrence of thyroid disease in the north central states of this country. Is the distance from the ocean a factor and can the systematic supplying of iodine in iodids diminish the incidence and, thus, decrease the frequently damaged heart? School children of northern Ohio have shown great benefit from the small frequent doses of iodids. Does the result warrant the continuation of the method and, under what conditions? If careful consideration reveals evidence that the method has value, then a wider distribution of the knowledge of physicians in the area would be justified and could be made feasible. Is there any relation between the causation of simple goitre and toxic hyperthyroid conditions? A careful research would well repay in life. What part, if any,

do geological conditions play in the causation of, or freedom from, heart disease or endocrine insufficiencies? Do the earlier geological areas affect the incidence of thyroid disease? Do such conditions account for the toxic goitres and heart damage, and if so, by what method may the damage be prevented?

### Need for Intensive Survey

Why do the colored races in our cities have a much larger incidence of heart disease than the white race living in the same areas? Does the pigment of the skin prevent beneficial effects of the sun's rays, just as window glass will prevent the beneficial effect of the sun on rickets, gangrene, and other diseased conditions? What factors determine the shortening of life expectancy by heart disease in the colored of both sexes, so that at the age of 35, it is 2.23 years in the male and 2.60 years in the female? Why do white females suffer greater curtailment of life expectancy up to 24 years of age while the men suffer more after the same age? Does open air life with exposure to the sun's ultra violet or other actinic ray account for the differences? Do economic conditions of poverty and wealth or inherent excesses play a large part in the causation of heart disease and how much may a persistent campaign of education among any group or nation be expected to reduce the mortality and incidence of the disease?

A close analytical study may be able to discover if it is true that heart disease is transmissible from parent to progeny and what factors determine such propagation; is it a mendelian unit, and what breeding conditions may favorably influence? Applied eugenics may be the only answer. A minute widespread investigation of the life conditions under which the children with heart disease have developed the damage may reveal some common factors which may be isolated and the knowledge practically applied with a definite effect by preventing further incidence. An intensive study of occupations where there is a prolongation or frequent recurrence of subjection of the individual to excessive forces involving muscular or mental endurance, high or low or greatly varying degrees of temperature, may yield information of value in preventing injury to others.

There is room for analysis of all the evidence bearing upon the relation of focal infection to damaged

heart tissue. There is evidence suggesting that the removal of infected tonsils diminishes the subsequent incidence of joint pains and rheumatism, but there is little or nothing but assumption to show that the tonsils act in any way than as portals of entry.

In the care of children who have infectious diseases, there is a very great opportunity for the family and physician by better and earlier quarantine to reduce the number of other children who become infected. To what extent better and more individual care will effect the incidence of heart disease among children remains to be determined by actual trial. In this connection it is interesting to note that in the histories of a group of children considered normal on physical examination, 58 per cent had had measles, 33 per cent pertussis, and 18 per cent one or more attacks of tonsillitis. Compare these findings with the history of a group of children who had organic heart disease and one discovers 64 per cent had tonsillitis, 45 per cent rheumatism, 36 per cent measles, 18 per cent pneumonia, 17 per cent diphtheria, 14 per cent chorea, 13 per cent pertussis, and 12 per cent scarlet fever. From the above, one may infer that a greater watchfulness, and possibly prolongation of the convalescence of such disease, may definitely prevent damage to the heart in children. Certainly a better quarantine should diminish the spread of the children's diseases for it has been shown that increasing age tends to reduce the probability of infection by these diseases.

Even the common "cold" and mild attacks of grippe or influenza may well be the start of serious heart damage. The general estimate of the harmlessness of such infection should be revised in view of the fact that a week's illness from such infections may require five weeks of convalescence before there is complete recovery to previous energy production. There must be a revision of the opinion as to when complete recovery from infectious diseases may be considered to have been established in order that damage to the circulation may be prevented. It is the duty of physicians, therefore, to prolong the period of convalescence and to teach the necessity for such care, in order that the fear of consequences which is first inculcated be replaced by the satisfaction of faith in the knowledge of prevention.

The specific selection of the syphi-

litic spirillum and virus for the blood vessels and heart is common knowledge, and the prevention of this damage is so involved in the campaign against venereal disease that it seems scarcely necessary to mention, yet if more emphasis were put upon this phase of the physical damage by syphilis, possibly less frequent infection and heart damage might result.

The disappearance of typhoid as a public health problem has removed a source of circulatory damage and made a beginning in real prevention of arterial disease.

A wider use of knowledge already available concerning methods of living, both for the individual and groups, their occupations, and the conditions under which they work, would make for better community health. The better use of leisure time in sports, recreation, and avocations might well prolong the efficiency of the circulatory system. A better regulation of the frequency, amount, and variety of food eaten may be a factor in eliminating certain types of deleterious conditions responsible for the production of heart impairment.

#### Recapitulation

The scope of the work for prevention is seen to be very broad. Few of the possible methods have been studied and not all the known methods are generally applied. To recapitulate, heart disease incapacitates a large number of our population and is the cause ascribed in an increasing proportion of deaths. The numbers of the population involved directly or indirectly is so large as to warrant an early and extensive investigation of the situation. Since there is an apparent increasing death rate, there must be some way to overcome the active agent. To determine what forces are acting, there must be a careful record made of all cases of heart disease over as wide an area as possible, the wider the better. Such a survey must enlist every branch of science and include an analysis of living conditions, climate and housing, personal, family, and city habits as well as the methods and conditions of occupation and recreation.

The knowledge already available must be practically applied and broadcasted to the physician and public. The profession can raise its standard of quarantine, care of infectious disease, and prolongation of convalescence. In prevention lies the opportunity for the greatest good to the individual and to the community.

## Educational Movie Rules in Pennsylvania

After a year of public discussion and consideration by a special committee and members of the Industrial Board of Pennsylvania, the special regulations governing non-theatrical exhibitions of motion pictures were adopted on May 9 to be effective September 1, 1922.

The principal feature of the regulations is the distinction between the flammable (nitro cellulose) and the slow burning (acetate cellulose) films. As a requirement for the non-professional use of flammable film in approved fireproof booth must be provided before permits for operation may be issued.

The regulations are being published in a separate pamphlet as Supplement No. 1 to the Safety Standards on Motion Picture Operation. The rules apply to all motion picture exhibitions before public assemblies except in theatres, opera houses, motion picture houses and factories or other industrial establishments in communities other than cities of the first and second classes.

Two general types of motion picture projectors are recognized, according to whether they are to be used with both types of film or with only slow burning films. Permits for operators and use of buildings for motion picture exhibitions are similarly classified to type of film to be used. All slow burning film to be used with approved projectors shall be marked to indicate that it is slow burning and manufacturers of such film may be registered for products and markings with the Industrial Board. All motion picture projectors shall be approved by the Industrial Board before being installed or operated.

An applicant for a permit is required to file his application, accompanied by affidavit. Permits are effective for one year unless revoked.

Permits must also be obtained for use of buildings where motion pictures are exhibited under these rules. Two classes of permits may be obtained; one, covering building or rooms in which flammable film may be exhibited. Such permits will be issued only when approved fireproof booth is provided unless in case of exhibitions before the sick, aged, infirm or other "shut ins," the Industrial Board specifically rules otherwise; and two, to cover buildings or rooms in which only slow burning film may be exhibited.

# Education—A Factor in Health Promotion\*

## Faith in Early Training Gives Permanency to Health Education in the Public School

BY C. E. TURNER, M.A., C.P.H., ASSISTANT PROFESSOR OF BIOLOGY AND PUBLIC HEALTH, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, BOSTON, MASS.

AS MEMBERS of the public health profession we are interested in health education as a means of reducing mortality and morbidity rates and as a measure by which vigorous health may be promoted. We grant, of course, that a knowledge of hygiene and sanitation should be a part of the equipment of knowledge supplied by any educational system, but the health officer's primary interest begins only when this knowledge comes to play a part in community health through its effect upon the lives of individuals. Knowledge must affect conduct before this result can be achieved, and we might do well to consider the educational opportunities before us in the light of this fact.

It is not difficult to show that there is no direct and proportional relationship between knowing and doing. If there were, a man's character would vary exactly with his knowledge of right and wrong. It does not. If there were such a relationship doctors' children would never lack medical attention, health officers would have a perfectly regulated and hygienic daily schedule, and shoemakers' children would always have shoes.

Under what conditions does a knowledge of how to live become sufficiently vital to affect conduct? What is the foundation upon which we are to build our health education program? In the first place we must think of *training* rather than of merely *informing* the individual, for we can never be sure of credit for improving the public health through education until we have seen the newly acquired knowledge translated into habits of living. But interest is as basic as training is necessary. The people with whom we deal are not under military discipline and we cannot train them by command. We must, therefore, rely upon their interest to secure the necessary motivation, and it is difficult to create interest in the person whose mind is centered upon affairs remote from the subject in hand.

Would you be interested to go out

*We are too sanguine if we rely upon chance to evolve positive health and wholesome habit. Right method in other fields is painstakingly developed year by year. So in health matters, visual appeal, dynamic interest, and the precision of oft repeated process must be enlisted to promote the desired state of positive health.*

*The beneficial results of health training are immediate, and they become habitual and permanent in the communities which subject their children to a perfectly regulated and hygienic daily schedule.*

to the street this minute and receive instructions from an expert in the art of backing an automobile? Probably not. There are only two times when you are interested in backing automobiles—when you are learning to drive in order to secure your license, and when you get stuck in a tight place and long for more skill. When are you interested in what will stop a baby from crying? On two occasions—when you are a crying baby, and when it is up to you to quiet one. When are you interested in the technique of infant feeding? First, when you are the infant to be fed, and again when it devolves upon you to prescribe the formula or prepare the modified milk for an infant's diet. Similarly there are two periods when people are primarily interested in learning how to live. The first period is that in which they are receiving their general training for life in the public school, and the second is the period in later life when they perhaps get into trouble because of lack of information. Similarly, on the basis of interest, popular health education may be divided into two distinct phases—the education of children and the education of adults.

I shall deal very briefly with the popular health education of adults. To secure their interest is both difficult and necessary. We should take advantage of the special health interests which they develop from time to

time and the foregoing discussion of basic principles suggests a division of adult instruction into three varieties.

(1) *Personal contact* may be secured by public health nurses, physicians, and the workers at health centers or clinics. The information from these workers goes to a person seeking advice. It is authoritative, personal, applicable, and direct. It is the most expensive but by far the best method, since it trains people in the correct manner of living at a time when they are most amenable to training.

(2) The use of specially *timely information* is perhaps next in value. Examples of this type of instruction are seen in the sending of infant welfare booklets following birth registrations, the distribution of information for the control of communicable diseases at the time houses are placarded, or the use of the press and special pamphlets at a time of threatened epidemic. Here the personal contact is lacking but there is still the advantage of supplying information to particular individuals or groups when they are anxious to receive it and can immediately put it into practice.

(3) *Broadcasting* health information by pamphlets, lectures, exhibits, motion pictures, or wireless telephone, is the other variety. Here the elements of personal need, personal contact, and preformed interest are all lacking. This method carries the lowest per capita expense, but for the reasons mentioned it must also be least effective. The manner of presenting the information must be so unique and pleasing as to arouse interest and the message must be so strongly put as to motivate the individual. Otherwise, habits of living will not be affected. The motion picture is perhaps the best example of a method which has such high attention value that it robs the learning process of the "painfulness" which it possesses for most people. Showing a good health movie is like using fresh fruit medicinally. The spectators enjoy it and it is good for them. In general, however, the broadcasting method varies in its success according to the interest-bearing value of its mode of presentation and in proportion to the number of people in the community who are actually at work in putting the program across.

The health education of the child is an even more important task than the education of the adult. Here is the greatest opportunity for health teaching, and it has been too much neglected.

You may have been interested in

\*An address delivered before the New England Health Institute, Hartford, Conn., May 4, 1922.

industrial health and the educational possibilities in industry. Suppose you had in your community one industry which employed one third of your total population. Suppose this organization were willing to give an hour a week of the company's time for training its employees in health. Assume the general manager to be interested in health, an old acquaintance of yours, and employed by the same people for whom you had worked. Suppose, further, that every one in the industry would go home and tell at the supper table the special health lesson they had learned each week. What would you think of that opportunity for health education in your community?

Such an industry really exists in your town. It is the public school. The school superintendent and the health officer are working for the same people, and the best results can be obtained by a liaison between the health and school departments. The logic of this becomes apparent when we realize that health training for children is only a part of the complete school health program which includes disease prevention, the correction of defects, and health promotion.<sup>1</sup> The whole plan should be kept in mind in working out any detail, and the development of a complete plan with a clear and distinct understanding of the distribution of activities between the two departments is a much needed step which many communities have not yet taken.\*

There are many reasons for the instruction of children in hygiene and sanitation. Such instruction would undoubtedly be worth while if for no other purpose than to provide the individual with such fundamental knowledge. We might hope and expect that somewhere in later life some of this knowledge would be found useful and therefore have an effect upon the public health, but if it can be shown that training in hygiene will improve the *present* health of the school population and strengthen the other activities of the school health program, then, indeed, it has a *raison d'être*.

It was a belief in such a possibility which prompted the experiment made by the writer in Somerville<sup>2</sup> and the

studies now being made in Malden. We know that the child with incipient tuberculosis can be placed in a sanatorium where his food, rest, and daily schedule are properly arranged, and that without medication he gains in weight and strength. We know, also, that through the work in mouth hygiene children have been trained to take better care of the teeth. With these two facts in mind it seems highly probable that the school child may be trained in other habits of living and that such an improved regimen would favorably affect health. A belief in this possibility is strengthened if we understand the serious and implicit faith which the child places in what he is taught at school. The influence of the teacher and the activity of the other pupils in his grade is often a stronger force in compelling right action on the part of the child than the command or entreaty of the parent. In the public school alone do we have the aid of long continued example, practice, repetition and reiteration in driving home health truths.

#### Health Training Counts

The benefit of health training is demonstrable by growth records. This is not the place to go into a discussion of the right use and wrong use of standard weight tables. But at all events it is clear that growth is a normal process for the healthy child and when we found in Somerville that in a group of children receiving health training for the year only one pupil out of a class of thirty-nine failed to make an average growth gain, whereas in two control grades of the same size, where health training was not carried on, nine and sixteen children, respectively, failed to make a normal growth gain, it seemed clear that the adoption of health habits had produced the desired effect. The results of our present studies in Malden are not yet available for publication. We do know, however, that of 247 children who were below average weight for their age and height and who received health training, 118 were nearer the normal at Easter than in November. In a control group, where other conditions were the same but where no health training was carried out, there were 141 children below average weight, and of these only thirty-seven improved their condition

in the time mentioned. In other words, among underweight children receiving health training 118 made a definite gain toward normal weight for their height and age, while 129 stood still or lost. In a similar group which did not receive health teaching thirty-seven made a gain while 104 stood still or lost.

The work carried out with these pupils was non-medical and untechnical. It involved the work of a well trained teacher who first enlisted the interest of the child in the positive factors of health, such as growth, strength and beauty, and then trained the children in the important health habits through classroom teaching, the keeping of habit records, the making of scrapbooks and the carrying out of other projects by the children, and occasional talks with some of the children about their own particular needs. Regular weighings and the observation by each child of his own growth record were important factors in stimulating the child to improve his mode of living. The health teaching was to some extent correlated with the teaching of other subjects in addition to the thirty to sixty minutes per week given to the subject itself.

We may hope to have from various parts of the country within the next few years ample confirmation of the value of health education in the public schools in terms of immediate health improvement. In any case we can hardly neglect the responsibility not only to take care of our physically defective children but also to provide a unified program of sound instruction for *all* children, with the very definite expectation of a considerable benefit to the entire group and a consequent reduction in the number of children who need special corrective treatment. A city certainly has much to hope for from a well arranged and properly supervised system of health instruction which deals primarily with motivation and health training for the first four grades and in a suitable fashion provides more organized instruction in health habits, bacterial cleanliness, disease prevention, community hygiene, first aid, home nursing, and applied physiology in the later years.

At the annual convention of the Baltimore and Ohio Association of Railroad Surgeons which was held in Chicago recently a campaign to inform railroad employees of the danger of contagious and social diseases were initiated.

\*Recognizing clearly that health instruction is only one phase of school health work, which includes many other important activities, it is not possible to discuss here either the nature or relative importance of the other phases. It would be most regrettable, however, if the necessity of limiting the scope of this discussion should educe the wrong conclusion that the writer believes health education is the one and only important activity in the school health program.

# Institutional Farms for Convalescents

BY WALTER E. WRIGHT, ASSISTANT DIRECTOR, THE BURKE FOUNDATION, WHITE PLAINS, N. Y.

**M**ANAGERS of new institutions and of established ones which are situated in open country or have unused land areas repeatedly bring up the question of more gardening or general farming upon their plots. The proposals, usually made by new members, appear enticing and it is often wondered why the superintendent and others with experience advise delay or caution in the matter.

A recent collection of figures, general statements, and personal opinions from those in charge of twelve institutional gardens and farms within our fifty-mile radius leads to the conclusion that they average an actual slight to moderate loss over a series of years. In most instances the agricultural accounts are not accurately kept, and precise incomes and expenditures are with difficulty separated from the general running expenses mainly because of the intricate, and proper, interactions with the other activities. The larger state insane and custodial places are not included in this study, but scanning and just interpretation of their reports will disclose surprisingly narrow margins of farm profit or loss, even though they are favored with abundant free or part-free labor.

Certain general facts partly clear the problem in the beginning. Small private farming on the average and under the favoring conditions of home-group and long-hour help yields good livings only, with but scant, if any, net income; most institutions in question are located suburban to cities and are wholly under the influences of high wages, high cost of material, short hours and the accepted inefficiencies of this environment; the soil available is apt to be "run-out." "Plant-enemy" and the various neighborhood depredations are here at their height. The rapid subsidence of the "war-garden" effort applies here; many factors have of course caused this, but the main one is that it didn't pay. The people are not slow to stop a money loss, nor in further developing a clearly profitable work near at hand. New managers of institutions who so often propose to "grow their own vegetables and save much expense" are measurably mistaken.

Why, then, do the older places continue to conduct gardens and general farming? Because of definite gains other than money-profit. Should new

country health institutions, large or small, plan some tillage of their land? Yes; and mainly for the following reasons: "vegetables from our own garden," the "pure milk of our dairy," are phrases back of assured values and mean advancement for the institution; the sight and feeling of an abundance of these particular products induces in practice a better balance of institutional diet, as noted especially in the light of the newer food facts (cheaper vitamins); employees, too, appreciate the combinations and are more contented; a balanced amount of this land culture makes feasible a better staff for house and grounds care and the many intermediate duties; details of many advantageous "help" combinations, extending from garage and stable through land-care into heating plant and house service, will suggest themselves. Tillage gives charm and finish to the neighborhood as compared with unkempt areas, and supporters of the establishment like to see it in such

It is not practicable to try to present accounting figures of the institutions in the present inquiry, further than as summarized in the beginning. A very large private hospital for mental diseases, having a long-established organization with large acreage, reported profits one year and losses another, one made first claims of big profits which analysis mainly dissipated (a common error); milk production in the larger plants seemed to present most general satisfaction. Each place has found by experience a suitable ratio of garden to other activities, and none would quit the procedure because the sure auxiliary advantages outlined above outweigh moderate monetary losses.

The Burke Foundation's Convalescent Home, maintaining 300 patients and 100 employees upon a sixty-acre plot has, after seven years' experiment and fairly accurate accounting, settled to a ten-acre farm-garden with no live stock. Monetary profit of a few hundred dollars per year is fig-

A group of stronger, hungrier boys returning from their work at the convalescent farm.

full-rounded adaptation; tax exemption not infrequently hinges upon the full or part use of the property for the charitable and remedial purposes, and good-feeling may be upbuilt by gifts of surplus product in season to neighboring charitable organizations. But of more importance, perhaps, than any of these is the occupational and mental therapy which farm and garden may furnish wherever the patients are convalescent or but partially handicapped, physically or mentally.

ured for the whole period, but this fails to take account of the various depreciations, insurance, etc. Value of the yearly product has been from \$3,000 to \$5,000; about one-third of all the fruits and vegetables used are thus supplied. The organization has been simplified until one head has charge of the garage, gardens and grounds. The obstacles to precise gardening accounting are well illustrated here by the frequent changes of men and horses from garden to lawn-care, to transportation of patients and sup-

plies, etc. Many patients working moderately one or two hours per day have benefitted health but not farm expenses to any extent; a part-pay occupation for some as they gain strength has proved good mental and physical therapy only.

that horses can do most of the work, the labor-cost being ever paramount in a suburban environment. Artificial fertilizer is used freely in lieu of cheap barnyard manure; plowing under fertilizer crops is worthwhile at times.

Cardiac adolescents under supervision are strengthened and group-trained by garden work.

Kinds of crops raised will depend upon land, labor, possible interacting organization and equipment, and the appetites and needs of the particular patients accommodated. A list for this zone may be approximated: lettuce, sweet-corn, onion, radish, tomato, carrot, turnip, parsnip, parsley, cabbage, celery, rhubarb. Potatoes are best bought unless exceptional conditions obtain. Asparagus and strawberries may come into favorable schemes.

The technic does not always closely follow that of the market gardener but aims to arrange crops so

A very common cause of dissatisfaction and partial failure is lack of hearty and painstaking cooperation between dietitian and gardener, resulting in wrong plantings and crop rotations, surplusage, kitchen waste, expensive seasonal lacks, and at times unbalanced diets; someone placed over those in charge of each section obviates this. We concur heartily with the institutions canvassed in saying that we would continue the gardens even at a moderate financial loss for the sake of the health and contentment and sentimental gains accruing thereby, as indicated previously.

## Unusual Human Foods

THAT the civilized human being has by no means exhausted the possibilities of food variety is shown by Professor Albert M. Reese of West Virginia University in *The Scientific Monthly*. Many animals make acceptable food but are not eaten for reasons of prejudice. Among the mammalia which would make acceptable food for men are mentioned monkeys, peccary or bush-hog, opossum, woodchuck, muskrat, whale.

That the English sparrow might well grace the festive platter is the contention of the writer. They are easily prepared and when properly roasted taste as good as the famous reed-bird. Eating the birds would reduce their numbers and consequently minimize them as a pest.

Edible birds' nests, formed of the

dried saliva-like secretions of birds, when cooked are considered by the Chinese to be a great delicacy. Experimental preparation, however, revealed only a gelatinous mass of little taste.

Reptiles as an article of diet have always aroused strong prejudice. Alligator meat, however, has been served much as breaded veal cutlets and enjoyed by civilized humans of discriminating taste. Turtles are an accepted food while turtles eggs are extensively used in the tropics.

Prejudices against amphibia as food are also marked. Although many consider frogs' legs a delicacy, they will not consider eating the larger salamanders, or alligators. Fish is a readily accepted article of diet, but there is still a popular prejudice

against sharks; and whereas lobster is liked by many, crayfish is not touched.

Fresh water mussels might also be added to the diet of the average person. Owing to the pollution of the streams in which they live, they should always be cooked.

Stefansson, the arctic explorer, says that the reluctance of people toward eating untried articles of food is oftentimes commensurate with their social status. "Well brought up" men, used in their homes to a large variety of foods both domestic and imported, take very readily to any new thing such, for instance, as seal meat," he says. "But men 'poorly brought up,' and used only to half a dozen or so articles of food in their regular diets, are generally very reluctant to try a new food unless it has been represented to them in advance as an expensive or specially delicious thing." The man of the laboring type feels degraded when compelled to eat the food of 'savages,' states Stefansson, while the man of intellectual type is appealed to by the mild flavor of adventure in experimenting with 'native food.' Eskimo women were much slower to try new kinds of food than were the men, he further discovered.

## Man-Made Malaria Hard to Eradicate

The task of eradicating malaria, says the United States Public Health Service, has been made doubly hard by the continual creation of fresh mosquito-breeding places by impounding water either intentionally or unintentionally—for instance, in the course of highway or railway construction. Owing to this, a considerable portion of the malaria in the country may be termed "man-made." Assistant Surgeon General Carter has found that probably three-fourths of the malaria in a district in eastern Virginia came from such artificial pools and swamps.

Man-made malaria is of special importance at present because of the recently enacted Federal highways act, which provides many million dollars for building additional good roads in the South. The specifications require that the culverts on these roads shall be so placed that they will completely drain all wet areas above the culvert entrance and that all borrow pits or excavations made along the roadways shall be filled or properly drained. No road, however necessary for travel, can be called good if it interferes with proper drainage.

# Social Measures in Venereal Disease Control\*

## Wherever Civilian Responsibility Has Been Assumed Control Has Followed

BY VALERIA H. PARKER, M.D., EXECUTIVE SECRETARY, U. S. INTERDEPARTMENTAL SOCIAL HYGIENE BOARD, WASHINGTON, D. C.

THE trend of modern medicine is toward the development of prevention of disease rather than toward placing the emphasis solely on diagnosis and treatment after exposure. In no field of medicine has the value of preventive measures been so strikingly proved as in the field of venereal disease control. The development of the protective program has been defined under the general term "Social Hygiene." It was not so long ago that the words "social hygiene" were considered a term to be spoken with bated breath. The words "syphilis" and "venereal disease" were banned from the more public prints which were available to everyone. Newspapers for example, would not carry any story in which a phrase such as "social disease" was used. But times have changed and we are in a new era of frankness which will lead to a better understanding of life, and which will remove the blanket of ignorance, prejudice and fear which has enshrouded the subject of sex. In place of the old policy of silence there has appeared an increasing recognition that social health is in a large part dependent upon the understanding and protection of those forces upon which family life and parenthood depend. The guarding of those very life forces is the field of "protective social measures," a field which should command the earnest study and effort of all groups bending constructive energy toward forwarding human welfare and happiness.

In order to appreciate the advance evidenced by the present aspects of the social hygiene movement, it is well to pass hastily over its history. It was started first purely on moral grounds by such organizations as the National Women's Christian Temperance Union, the Purity Federation, and other organized groups of far seeing and fearless men and women who based their beliefs in a single standard of morals entirely on ethical grounds. It was many years be-

fore the silence of the medical profession was broken by Dr. Prince Morrow. By written and spoken word he denounced those physicians who permitted innocent persons to become infected with venereal disease rather than to violate the principle of medical ethics known as professional secrecy.

His book "Social Diseases and Marriage" did much to enlighten the lay mind as to the magnitude of the venereal disease problem and the needless waste of health and life through blind ignorance. Dr. Morrow was the founder of the society of Moral and Sanitary Prophylaxis, and of the American Social Hygiene Association which has carried the movement into its present phase.

In 1914 the Bureau of Social Hygiene through Dr. Abram Flexner published a scientific investigation of the segregated vice districts in European countries. These findings showed the utter fallacy of attempting to license and give so-called sanitary protection to vice.

As a result of this study many of our larger cities appointed vice commissions. Following their investigations and recommendations a number of notorious segregated districts were closed. The apex of the pre-war movement against vice and its resulting diseases was reached when the organized physicians of the country proclaimed by formal resolution that continence for men is not incompatible with health. We approached the crisis of the world war with a quickened and aroused national conscience.

During the long hot summer months of 1915 when the United States troops were mobilized on the Mexican Border large numbers of men were stationed near wideopen towns where liquor was freely sold and where the lowest type of brothel existed. Few opportunities for wholesome recreation were available. No libraries where books could be had, no place for meeting a woman relative, nothing of this nature was provided the troops.

In command of the men were two classes of officers who may be said to typify fairly well public opinion as it

is found today. The old line army officer believed the demand for prostitution to be a natural one. He bent his energies mainly toward the provision of medical facilities for disinfection or early treatment after illicit intercourse. The more modern commander, however, believed in reducing disease by preventing exposure and was concerned with the morale of his troops as well as with the physical damage of the brothel.

In this latter group was an officer from Brooklyn who became much concerned when he learned of the flagrant vice conditions in the town near which his regiment was stationed. He first called upon the mayor and city officials requesting them to close the saloons and brothels to the United States troops. These officials smiled and shrugged their shoulders, stating quite frankly that they expected to make large sums of money while the United States troops were there and certainly would not close the places in question.

This officer took military action upon his return to camp. He ordered military police guards to be stationed around saloons and brothels, declared these places "out of bounds" and told the guards to prevent any of the boys from entering the places. This particular officer brought back his entire regiment without a single case of venereal disease. It was an unheard-of record, and his methods immediately attracted attention in Army medical circles, as venereal disease was the worst enemy the army then faced.

Reports as to these conditions on the Mexican border were made by Mr. Raymond Fosdick, later Director of the Commission on Training Camp Activities of the War Department, and Dr. M. J. Exner of the Y. M. C. A. Dr. Exner's report entitled "Prostitution on the Mexican Border" may still be secured through the American Social Hygiene Association, of which Dr. Exner is now educational director. His report shows how large numbers of immoral girls and women followed our troops to the border, and how in some instances they were housed in shacks built with

\*Read before the New England Health Institute, Hartford, Conn., May 1-6, 1922.

United States Government funds, certain officers setting aside women for their own use.

The above facts and the alarming increase of venereal disease among troops already engaged in the World War were factors in leading our Government when we entered the war to become the first in the history of all nations to adopt a program of moral protection for the men of the fighting forces which made no compromise with vice. The main points in that government program have a direct application to the social hygiene problem as it now stands and to the field of "protective social measures" today. These points are:

(1) *Education.*—Realizing that the majority of the men of the fighting forces had received no constructive sex education, the Government, through lectures, moving pictures, and literature endeavored not only to teach the dangers of venereal disease but to lay stress upon the fact that continence is compatible with health and fosters greater virility.

(2) *Law Enforcement.*—Definite zones were established about military camps and naval bases within which all sale of liquor and commercialized prostitution were prohibited. A Committee on the Protection of Girls was established. Trained and experienced women were sent to military and naval centers to guard the careless, thoughtless girls who flocked to those centers as well as to detect the professional prostitute.

These women were able to avert many a tragedy. Where tragedy had already begun, the circumstances were frequently mitigated. Since many states had no provisions for the detention of delinquent women other than the jail, where there were no facilities for moral or physical rehabilitation, a Committee on Women's Reformatories was established through which government funds were expended in assisting the states to provide proper detention facilities.

(3) *Medical Measures.*—During the years immediately prior to the war improved methods of diagnosing and treating venereal disease had become known to science. This resulted in great benefit to the armed forces. For those who were uninfluenced by educational measures, stations for early treatment or prophylaxis were provided in the hope of decreasing the incidence of venereal disease.

Some of the medical officers were so impressed by the marked reduction of venereal disease that they ascribed it entirely to the prophylactic station. A prominent surgeon recently advocated at a public meeting in Washington, D. C. the establishment of civilian prophylactic stations, recommending that one be placed in every

High School and College. I feel confident that his recommendation will not receive popular support.

(4) *Recreational Measures.*—Recognizing the need of wholesome outlets for the splendid energies of the young men of our fighting forces, the United States Government secured the assistance of seven voluntary national organizations in the promotion of recreational and athletic facilities. Libraries, club houses, theaters, hostess houses for meeting mothers, wives, or sweethearts were erected inside the big camps. Clean amusements were brought directly to the men, for the first time in the history of the Army.

#### A Civilian Responsibility

That this comprehensive program had weak points is unquestionably true. It came too late in the lives of many who had already formed habits of incontinence. There were some officers who did not believe in the program and who emphasized the value of the prophylactic system rather than the desirability of continence. The temptations overseas were more open and flagrant than in most of our own communities. The fact remains, however, that the United States sent into the World War the cleanest army of men in body and in character known in the history of warfare.

Unfortunately, this was not the result of American training in home, church, and school. The draft figures which revealed so many of our national weaknesses showed 130 out of every one thousand of our drafted men to be infected by venereal disease. Examination at the time of discharge showed only one-sixth as many men to have become infected after entering the army and navy as were infected at the time of enlistment.

This emphasizes the fact that the problem was and still is, essentially a civilian responsibility. It is one which every intelligent and right thinking citizen must aid in solving, if we are to gain permanent results. We must promote wholesome and constructive instruction of parents, both present and future; the introduction of sciences in elementary form in the grammar schools; provision of a proper sex vocabulary to replace the ever present vocabulary of filth and obscenity common to the street and school yard.

While we are concerned with the low standard of morality evidenced in certain public amusement places such as dance halls and moving pictures houses, we must not ignore the fact that recreation is a vital necessity to

the young. The provision of increased recreational facilities of a wholesome character under proper supervision is a present day problem.

The United States Interdepartmental Social Hygiene Board is one of the agencies established for the promotion of a nation wide program for the solution of these problems under discussion. It was established as a special government bureau in July, 1918. The members of the Board are the Secretaries of War, Navy and Treasury, and the three Surgeons General. The Surgeon General of the Army is at present Chairman of the Board. As a result of its work the army rate has been reduced from ninety to sixty-two. Navy authorities have stated that the Board's work is largely responsible for the drop in navy rates. Eighty-three red light districts have been closed during the past year as sources of infection. Cities and citizens have been put on their guard, educated to the dangers of social diseases.

At the meeting of the Interdepartmental Social Hygiene Board held in September, 1921, for the purpose of determining the amount of money to be requested from Congress for continuation of the work during the coming year, information was given that the work now being conducted by the Board would be provided for in the new Department of Public Welfare. The members of the Board accordingly voted not to ask for an appropriation. It has now become evident that the Department of Public Welfare will not be organized before the end of the present fiscal year, and bills have been introduced in Congress to carry on the work through the Department of Justice. Unless the bills are passed before June 30, on that date the active program of the Board must cease although the Board itself will still exist officially under the Chamberlain-Kahn Act which also established the Venereal Disease Division of the United States Public Health Service to which has been appropriated \$225,000 for allotments to state boards of health in promoting the Medical control of venereal disease during the coming fiscal year.

The greatest gain made during the past four years of intensive work is the breaking down of public apathy and silence, and the increasing number of intelligent men and women who are able to face social hygiene problems frankly, determined to carry the program against ignorance and vice to a permanent completion.

# The Anti-Plague Campaign in Pensacola\*

## Rat Proofing and Traps Employed in Combating Rodent Plague Carriers

By R. R. SPENCER, PASSED ASSISTANT SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

**B**UBONIC plague has been endemic in California since 1900 and in New Orleans since 1914. During the month of June, 1920, the disease broke out at three other seaports of the United States, namely, Galveston, Beaumont, and Pensacola. Within a few days, the Public Health Service, in cooperation with the respective state boards of health and local health departments, began suppressive measures at each place. The general policies and the methods employed were essentially the same at each port. The following account only describes the progress of the anti-plague measures at Pensacola, for a little more than a year.

On June 11, 1920, the federal quarantine officer at Pensacola, Florida, reported a suspected case of bubonic plague to the Surgeon General of the United States Public Health Service. The patient was described as becoming suddenly ill with a chill, followed by high fever and delirium, later presenting a very large swelling in the left femoral region. The swelling was aspirated and smears showed organism with typical morphology of *B. pestis*. Two guinea pigs were inoculated with the aspirated material and subsequently died, revealing typical pathological lesions of bubonic plague and the diagnosis was verified by complete bacteriological confirmation. Since plague had never been known to occur in Pensacola before, it was of great importance to determine whether the infection had been contracted locally or whether the patient had brought it in from some infected port such as New Orleans or Vera Cruz. The history showed that the patient had lived all his life in Pensacola and had not left the city or been aboard a ship in the harbor for the preceding six months. These facts together with the occurrence of a second case on June 15, and a third on June 18, appeared to be ample evidence that the infection was coming from local rodent plague foci.

At the request of the Florida State Board of Health the Public Health Service assumed charge of the situation and the laboratory car "Hamil-

ton" which was being used in conducting a rodent survey at Mobile, Alabama, was ordered to Pensacola with its entire equipment and personnel trained in plague work. The car arrived in Pensacola on June 17, and facilitated the immediate institution of plague suppressive measures.

Upon reviewing the city death records, it was found that a negro boy, aged sixteen, had become suddenly ill on May 31, and died two days later. Further investigation indicated that the case might have been plague. Accordingly, on June 20, the body was disinterred and the autopsy revealed

two and one-half months after the inauguration of plague suppressive measures.

The analysis of the ten cases of plague has not yielded any very conclusive results, but it may be mentioned that all were males and four were teamsters; that the diagnosis in each case was confirmed by the usual bacteriological methods; that two presented a cervical bubo, all the others being femoral and that there developed no contact cases or cases of the pneumonic type.

Each human case was isolated in the home, care being taken that rats the fleas were eliminated, so far as possible, around the premises. No attempt was made to isolate all patients in one building because the city possessed no adequate isolation hospital and because the bubonic form of plague is practically non-contagious from man to man.

Very nearly all eradication measures center around the location of plague foci. The location of human cases usually indicates the existence of an advanced rodent focus either at the patient's residence or place of employment. In Pensacola, foci were found at the place of employment in the majority of instances. Although there were many definite rodent foci from which no human cases developed, epidemiological data as well as the history in each strongly pointed to one or more of the rodent foci as the source of human infection. This fact supports the observation made by the Indian Plague Commission,† and confirmed by experience in all subsequent epidemics that plague is primarily a disease of rodents and only accidentally and secondarily a disease of humans. The epizootic continued long after the disappearance of the epidemic in spite of the intensive and continued destruction of rodents.

Thirty-six rats were diagnosed in the laboratory as having plague, or about .2 per cent of the total number of rats examined. These rats were recovered from twenty foci. Whenever a plague rat was discovered, an inspection was made of the prem-

Trapper's complete outfit, showing the steel snap trap, wire cage trap, etc. Detailed directions were given to trappers and bounty offered for each rat in addition to wages.

a left femoral bubo surrounded by extensive hemorrhagic injection. Organisms morphologically resembling typical *B. pestis* were found in the smears, but animal inoculations proved negative, possibly due to the bactericidal action of the embalming fluid. A more complete history afterwards obtained from the family and the attending physician established the diagnosis of plague beyond a reasonable doubt. The tenth and last human case occurred August 31, just three months after the first case and

\*Approved for publication by the Surgeon General.

†Journal of Hygiene, September, 1906.

ises where it was trapped. Such a location constitutes a plague focus and demands immediate attention. It was customary to treat foci either by fumigation with hydrocyanic acid gas, by demolition and destruction of rat harbors, by intensive trapping, by the use of a pulicide emulsion as a spray for ground areas or by two or more of these methods combined.

Demolition and destruction of rodent harbors is probably the most effective and quickest way to successfully attack a plague focus, but is, unfortunately, difficult and expensive in many instances. Treatment of foci, therefore, varied according to the practicability of carrying out these measures. Because of this, many buildings which were known foci and others which harbored many rats could not be considered clear of plague until many months afterwards when ratproofing of such structures was finally secured, sometimes only after court procedures. In this connection, it is interesting to note that three of the last four plague rats recorded were captured during the ratproofing of a grocery store under the floor of which they had remained protected for months. Fumigation will not kill rats burrowed in the ground under floors, nor is it feasible to destroy fleas in underground nests either by the use of fumigation or a liquid pulicide.

The methods of rodent reduction employed in this campaign in the order of their importance were, (a) ratproofing of buildings and premises, (b) trapping, (c) cutting off the rodent food supply, (d) poisoning.

It must be remembered that in a community of thirty thousand people, complete extermination of rodents cannot be expected with our present known methods; yet, by means of an intensive campaign and the wholehearted assistance of the citizens, there is no reason to doubt that the number of rodents may, in time, be reduced to such an extent that they will become a negligible factor in the propagation of plague. While ratproofing of all structures is believed to be the most effective and permanent method of rodent reduction, it requires a great deal of time and is a heavy financial burden on property owners. Moreover, it cannot be instituted on a large scale at all without the enactment of legislation and even then progress is necessarily slow. For these reasons, the immediate suppression of plague must largely depend upon trapping, poison-

ing, and the removal of food from rodents.

### Ratproofing Buildings

A ratproofing ordinance was passed by the city commissioners of Pensacola on July 8, 1920. This ordinance was modeled after a similar one in New Orleans, with a few modifications suitable to local conditions. For a detailed description of the proper methods of ratproofing, the reader is referred to the Public Health Reports of April 29, 1921.

It is sufficient for our purpose to state here that buildings are divided into two main divisions according to their uses: Class A and Class B. Class A includes food depots and all buildings where foodstuffs are stored,

Type of building flat on the ground and with defects in the area wall showing conditions which provide ideal homes for rats.

handled, or prepared. Class B includes residences and all other buildings not in Class A. The chief distinction in the manner of ratproofing is that Class A structures are required to be ratproofed by means of a concrete floor at least four inches thick and protected by an area wall at least eighteen inches in the ground, while Class B structures may be ratproofed as Class A or by elevation on pillars eighteen inches above the ground and the filling of the double walls with brick or other material impervious to rats. In the elimination of rodent harborages in a community, the ratproofing of Class A buildings is obviously far more important.

There were approximately 7,200 premises or main buildings in Pensacola. Of these, there was a total of 414 food depots. During the year 368 or 88.8 per cent of the Class A buildings were completely ratproofed. Twenty-four remained incomplete,

having installed concrete floors but possessed minor defects which prevented their being listed as complete.

Three thousand eight hundred and nine or 55.6 per cent of the Class B buildings were ratproofed during the same period. Over one-half of the remaining non-ratproof structures were well elevated residences which required only minor repair to bring them within the requirements, and practically all of them were in the non-infected area of the city. The tabulation given below shows the entire amount of ratproofing work accomplished to June 30, 1921:

Sq. yds. concrete floor laid.....	40,791
Linear feet area wall installed....	58,767
Linear feet flashing installed.....	6,901
Sq. yds. planking removed.....	40,414
Sq. yds. wire floor installed.....	15,388
Number of food depots.....	414
Number completely ratproofed.....	368
Per cent ratproofed.....	88.8
Per cent non-compliant.....	3.8
Number of structures other than food depots.....	6,868
Number completely ratproofed.....	3,809
Per cent ratproofed.....	56.9
Per cent non-compliant.....	20.4
Total number of premises ratproofed	4,195
Average cost per premise.....	\$91.06
Total cost of ratproofing.....	\$383,003.00

### Trapping Another Means

Trapping operations began on June 18, 1920, and continued intensively for more than a year. The entire city was divided into trapping areas of about four blocks each. Trappers were required to work within their own districts, to carefully tag each rat caught, to place them immediately in a purse string canvas bag or bucket with a tight fitting cover, and to dip all rats in oil before bringing them into the laboratory—this last, in order to kill fleas.

There are many different kinds of traps and devices for capturing rodents but success is due more to the diligence and industry of the trapper than to the kind of trap used. Wire cage traps, snap traps, and steel traps were the varieties used throughout the year. Trappers were closely supervised and every detail carried out to make their work efficient. Each trapper was provided with a complete outfit as shown in one of the illustrations. Besides this equipment, some trappers used terrier dogs and trench spades for the destruction of underground nests of Norway rats. From time to time, observations were made upon the habits of rats and the best method of trapping.

As a result of this, the following conclusions have been reached, the majority of which are supported by the experience of other campaigns. (1) Experience in this campaign indicated that more efficient trapping can be maintained by offering to the

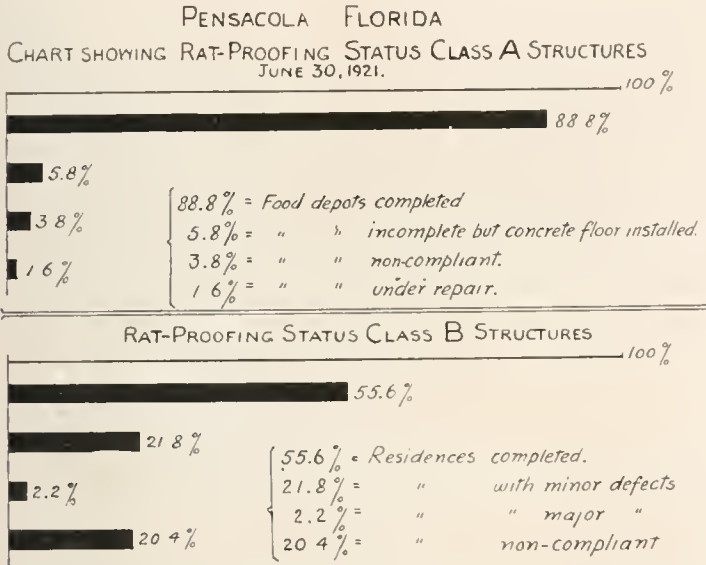

trapper bringing in the highest catch each month a prize of about ten dollars besides his regular salary and bounty of ten cents per rat. (2) The number of rodents in any com-

sidered good climbers, they have been trapped on the second floor of buildings and their nests with young have been found in the double walls of elevated buildings. (9) It is believed

1920, and in order to insure better collection and disposal extra wagons were put in commission by the city authorities. While this is the first step to be taken by the community as a whole, results always hinge upon the enforcement of the ordinance and the amount of cooperation displayed by the citizens.

Poisoning is another supplementary measure which will greatly aid in the reduction of rodents when discretely used. In the latter part of the campaign, 41,877 pieces of poisoned bread were placed on the city dumps, in gullies, ravines and other open spaces where there was considerable undergrowth. The preparation used was an arsenic paste. Within a few days after the distribution of the poison, about twenty-four rats were found dead. A larger number would probably have been recovered had not ratproofing and trapping been going on for some months. As a cheap efficient poison and less repugnant to rats than most others, the U. S. Bureau of Biological survey recommends barium carbonate.

Quarantine measures in plague work are directed against the migration of rats rather than against freight and persons. All cars were required to be ratproofed before loading, to be loaded only in the daytime, and the doors kept tightly closed at night. In the ratproofing and inspection of 5,623 freight cars only three rats were found. This small number can be explained by the fact that a very small percentage of outbound freight at this port consists of foodstuffs. Freight inspection was discontinued after December 31, 1920, when the

munity or neighborhood is determined by the available food supply. Excellent rat harborages have been discovered without any rats because there was no nearby food available. On the other hand, very poor harborages affording slight protection are often infested with rats because careless and insanitary conditions have provided a plentiful food supply. (3) Rats have been observed coming in and out of doorways of food depots after the buildings had been ratproofed. This demonstrates the necessity of flashing all doors to such buildings with sheet metal and closing tightly at night when unoccupied. (4) Large numbers of rats have been trapped in ratproofed depots whenever nearby non-ratproofed property furnished comfortable harborages. (5) In the neighborhood of ratproofed food depots rats are not infrequently found under the sidewalks whenever the pavement does not extend out to the curbing or back to the wall of the buildings. (6) Rats that have become trap-shy to ordinary snap traps and cage traps have been successfully caught by placing camouflaged steel traps in their runways. (7) The more a trap is concealed, the better chance of making a catch. After long unsuccessful trapping, rats have been caught by tying up tightly a baited cage trap in a burlap bag. The rats are then less suspicious and will cut through the bag in order to reach the bait. (8) Although Norway rats are burrowing animals and are not con-

Norway rats are filthier in their habits and prefer dirtier surroundings than do the house rats, *M. Rattus*. More fleas per rat have been found on *Mus Norvegicus* than on *Mus Alexandrinus* or *Mus Rattus*, and the *Mus Norvegicus* has a stronger tendency to cannibalism.

The protection of food from rodents is an effective supplementary method of deratization when universally carried out. The very first step in this direction is the passage of an adequate garbage ordinance, especially when the collection and disposal of garbage is lax. Such an ordinance was passed in Pensacola on July 6,

Even with the completely ratproofed buildings, sliding doors flashed with metal and fitting snugly in the groove of the concrete floor are necessary to keep the rats from coming in and out.

eptoötic was well in hand and all outbound freight sheds had been rat-proofed.

Maritime quarantine was under the supervision of the division of foreign and insular quarantine of the Public Health Service. All vessels leaving the port were required to be fumigated just before departure. Vessels mooring at local docks were required to fend off four feet and all mooring lines to have properly placed rat guards. Gangplanks were raised at night. These restrictions were removed August 15, 1921.

Publicity consisted briefly of special articles for the daily papers, lantern slides for the moving picture houses, window demonstrations of

plague suppressive measures in the business section of the city, distribution of hand bills to housewives, and other publicity connected with the inauguration of "Clean-Up Week" during March, 1921. The salient facts upon which emphasis was at all times made were (a) that plague is primarily a disease of rodents; (b) that plague is carried from rats to man by fleas; (c) that rats and fleas thrive in filth; (d) that plague is, therefore, indirectly dependent upon filthy conditions; (e) that cleanliness and sanitation will prevent plague, as evidenced by the fact that it seldom develops in the better and more sanitary residential districts of a community; (f) that it is within the

power of every individual householder and property owner to rid his premises of rats and fleas, if he will; (g) that rats are dependent for their existence upon the carelessness with which people permit food, garbage or animal feed to become available to them; (h) that the U. S. Public Health Service will gladly instruct and assist in ridding premises of these pests.

At the present time, no plague rats have been caught in Pensacola for more than seven months, and it is hoped the disease has been eradicated. Ratproofing, trapping and examination of rats are being continued on a smaller scale by the state and local health authorities.

## Malaria Incidence in the Panama Canal Zone

BY OUR LATIN-AMERICA CORRESPONDENT

STATEMENTS having appeared in the public prints to the effect that recent economies in the administration of The Panama Canal as the result of the recommendations of the Special Commission have resulted in an epidemic of malaria and fever among Panama Canal employees. The NATION'S HEALTH requested its special Latin-America correspondent to make an investigation of malaria conditions as they actually exist. This article which appears below was submitted to the Governor and to the Acting Chief Health Officer of the Panama Canal, and has received the approval of these officials. The data contained herein may therefore be considered as authentic.

The New York Times of July 5, 1922, quotes Mr. William C. Hushing, representative of the Canal workers in Washington, to the effect that: "It is time that the American public awakes to the fact that the wonderful sanitation program which General Gorgas installed on the Canal zone has been destroyed. The Panama Canal Commission which reported to the Secretary of War in October, 1921, said that the Canal Zone was too healthy and that sanitation should be reduced until the death rate was increased to that of certain cities in the United States. They ignored the statement of the employees that the death rate was low largely because sick people were returned to the United States."

After consultation with the Governor of the Panama Canal and the

Acting Chief Health Officer, Dr. D. P. Curry, I am of the opinion that "the wonderful sanitation program which General Gorgas installed in the Canal Zone" has not been destroyed. On the contrary, there is every evidence that the program laid down by General Gorgas has been and is being advanced in consonance with the best ideals of modern sanitary science. Many of the sanitary operations which were formerly necessary, have been discontinued because of the fact that permanent sanitary improvements have rendered them no longer needed. The policy of cutting grass about quarters which formerly cost the Health Department of the Panama Canal approximately fifty thousand dollars a year has been discontinued since it is known that malaria mosquitoes do not breed in grass but in collections of water.

The statement quoted above to the effect that there is an epidemic of malaria and fever among the Canal employees is not substantiated by the files of the Chief Health Office.

The following table, which was prepared by your correspondent, very clearly indicates this. (Table A).

An analysis of this table shows that the rate for all employees was less in January, March, and April of 1922, than during the corresponding months of 1921. The rates for February, 1921 and February, 1922, are practically the same. The only difference is seen in the rates for May, June, and July, of 1922, which are slightly greater than those for the corresponding months of 1921. An analysis of the rates according to "Gold,"—that is, white, and "Silver,"—that is, colored employees, discloses the fact that during the months of January, February, April, June, and July, 1922, the rate was lower among gold employees than in the corresponding months of 1921, and that for the silver employees the months of January and March, 1922, was less than in 1921; while the rates for February in the two years were practically the same. It is also evident from the rates for May, June, and July

TABLE A.—MALARIA INCIDENCE PER 1,000 EMPLOYEES, THE PANAMA CANAL

Month	1918	1919	1920	1921	1922

September	12,375	3,127	9,248	14	1.131	5	1.59	9	0.97
October	11,828	3,061	8,767	12	1.014	1	0.32	11	1.25
November	11,248	2,906	8,342	10	.889	1	0.34	9	1.07
December	10,927	2,759	8,168	18	1.372	7	1.64	11	1.09
1922									
January	11,014	2,691	8,323	12	1.08	4	1.48	8	0.97
February	10,795	2,640	8,155	14	1.29	5	1.89	9	1.09
March	10,568	2,628	7,940	6	0.56	3	1.14	3	0.37
April	10,538	2,598	7,940	3	0.28	0	0.00	3	0.378
May	10,272	2,557	7,715	17	1.65	4	1.56	13	1.67
June	10,176	2,553	7,673	20	1.96	4	1.56	16	2.09
July	9,942	2,569	7,373	22	2.21	4	1.55	18	2.44

of 1922 that the slightest increases which occurred among all employees were due to an increased rate of malarial infection among the silver employees; this is explained by the fact that there has been nearly a 50 per cent decrease in the number of employees during the past 19 months; the gold employees work on a full time basis, but many of the silver employees work only for short periods when there is work in connection with shipping; during the remainder of their time these employees are not under the control of the Panama Canal and visit unsanitated areas. This body of occasional employees is, however, carried as employees. The bulk of the "silver" cases, however, came from the Mount Hope district where new colored settlements have been opened up within the past year. The houses occupied by these laborers were screened and of approved sanitary pattern, but the employees who moved into them had previously been residents of Colon where houses are not screened nor are screens necessary in that city. These employees, therefore, were not aware of the necessity of the screens and in their ignorance tore them out, with the result that malaria occurred among them. These screens have been replaced and every precaution is being taken to see that they are maintained in perfect condition. It is believed that this measure will effectually control malaria at Mount Hope.

Table B, which sets forth the malaria incidence per thousand Panama Canal employees for the years 1918, 1919, 1920, 1921, and 1922 up to August 1, shows very clearly that the malaria rate for the year 1922 is far below the average rates for the same months of previous years, and it may therefore be concluded that an epidemic or an unusual prevalence of

malaria does not exist on the Panama Canal Zone. As a matter of fact, the malaria rates in the Panama Canal Zone are much less than in any part of the United States where malaria exists (Table B).

### Limitations and Authority of Local Health Boards

By Massachusetts law powers so great are conceded to the local boards of health that they make the board the most powerful branch of the government of which it is a part. Some of the powers and limitations, and some of the difficulties of determining the meaning of the law are fully discussed by Dr. Francis George Curtis, chairman, Newton Board of Health, in the *Boston Medical and Surgical Journal* of May 11. The chief functions of a board of health Dr. Curtis classifies under three major headings: nuisances, protection of food supplies, and the prevention of disease. At least 30 per cent of the calls coming to the average board of health are complaints in regard to alleged nuisances. Here the procedure is rather definitely prescribed, but limitations, too, are specific and it appears to be much easier to declare a condition a nuisance than to effect an agreement as to the manner of its abatement. Difficulties arise as well from the fact that, while the State Board of Health is invested with power to declare what diseases shall be classed as dangerous to the public health, the control of persons ill with such diseases and measures taken to prevent their spread are in the hands of the local boards, subject only to certain limitations by statute. Certain difficulties arise here for, if the board decides to quarantine a wage earner or prevent him from carrying on his usual business, he is entitled to compensation

during the period of his restraint equivalent to three-fourths of his regular wages, but this compensation shall not exceed two dollars a day.

Some difference of opinion exists as to the power of the Board forcibly to remove a patient to a hospital as set forth in Sections 95 and 96, and confusion may arise out of the fact that under certain circumstances the expenses of caring for the sick are valid charges against the place of settlement, but that any expenses incurred for quarantine and keeping people out of the house where the patient is, must be made by the board of health of the place where the illness occurs. Also, the board is limited to spending money for the care and support of the patient only and cannot take care of other members of the family. Certain questions of this character as well as matters of inspection could well be combined and the work divided between certain cities and towns interested.

As the chief method of increasing its necessary powers and reducing hampering limitations Dr. Curtis advocates care in handling satisfactorily the increasing number of questions which are propounded to the board of health. If the board will try to keep in close touch with its public and teach it to appeal to the board for advice on all matters connected with health, it will keep its public, professional and lay, behind it in its work.

The Illinois State Department of Public Health has just published a new bulletin on safe milk supplies which contains, among other things, a suggested form for an effective milk ordinance suitable for cities throughout the State. There is also a list of milk pasteurization plants operating in Illinois.

## Disease Transmission By Household Utensils

IN the dissemination of information regarding the bacterial origin of disease and means for the prevention of disease transmission, the fear of infection often outruns the judgment, and one often hears of patients who are afraid to go to a sanatorium, for instance, for fear of contracting further infection from others. The same attitude accounts for expensive and unwarranted efforts to isolate the sick from the well and for social ostracism in certain disorders which make a pariah of a sick man who is perfectly safe as a social contact.

Modern hospital methods have demonstrated the absolute efficacy of sterilization methods in infectious diseases and careful habit on the part of families and attendants makes it quite possible to handle contagious diseases safely in the home. Recent reports in *The Nation's Health* described the success of Dr. J. Allan Gray in handling scarlet fever in the home when hospital accommodation was limited, and the work of Dr. William Paul Gerhard in emphasizing the part of municipal sanitary regulation in the event of an influenza epidemic.

A recent editorial in *The World's Health* deals with the transmission of disease by household utensils. Referring to the work of Longstreet Taylor in investigating the transmission of tuberculosis by means of table utensils, it has been demonstrated that table utensils which have been used by tuberculous people do carry bacilli, and that remains of food found on their unwashed spoons and forks give tuberculosis to about 10 per cent of the guinea pigs into which they are injected. *The World's Health* goes on to say:

But it must be noted that these results are obtained before any washing has taken place. When the crockery and plate were carefully cleansed in a mechanical apparatus in which they are stirred about in boiling water and then dried with hot air, animals used for experimentation did not contract tuberculosis.

When sanatoriums are properly equipped, every guarantee against contagion and reinfection from patient to patient is provided, and the contamination of the personnel can be avoided by the use of mechanical cleansing apparatus. What is much more dangerous is the manner in which table utensils are washed in cafés and public houses. As Dr. E. E. Briau points out, hot soda water is most frequently used for the crockery, as it is the easiest way of clean-

ing greasy plates. It happens to be, at the same time, an excellent way of disinfecting. The problem is more complicated, however, for glasses, as hot water cracks common glasses; and in the conflict between respect for hygienic measures and the fear of breakage, he who holds the purse names the winner. In a great many establishments, the same glass may be used from 50 to 60 times in an evening and only be washed in cold water.

Dr. Briau describes the process as follows: "The dishwasher plunges the glasses and his hands into a zinc basin in which the water is renewed more or less frequently. The rim of the glass is held between the thumb and fingers of the right hand; the other hand holds the bottom of the glass and turns it two or three times in the fingers of the right hand—then all is finished, the glass is clean. At other times a bottle-brush is used, which is pushed into the glasses. This brush passes from glass to glass and between times lies in the water left in the basin. It is a repulsive object, with its slimy, worn-out bristles all glued together. Unfortunately it is very difficult to ascertain in how many cases diseases have been transmitted in this manner; nevertheless there are cases of syphilis of the mouth for which no definite cause has been found, and there are cases of gastritis, influenza, pulmonary troubles, even of diphtheria, which in all probability could be traced to the use of contaminated table utensils."

There are two methods which should be employed for the cleansing of utensils for general use and be enforced by any municipality anxious to preserve the health of the community, which are worthy of consideration: Dr. Briau advises the use of two basins of water, the first containing a strong solution of hydrochloric acid, which will destroy the organic germs without spoiling the glass. The dishwasher in this case must wear India rubber gloves. A second basin of running water will take away all trace of the acid. The use of hydrochloric acid would in the long run give rise to certain inconveniences, and it would therefore seem preferable to keep to the method employed, for example, at Leysin. There the plate and crockery are placed in metallic baskets, which are moved about rapidly in basins of boiling soapy water with soda in it. The movement backwards and forwards is obtained by means of an electric motor. The baskets are removed in succession into two or three basins, where they are successively rinsed and then dried. Glass is put by hand into hot water with about 50 per cent soap and 5 per cent soda. If this proportion of soda is strictly adhered to, every bacillus on the glass will be destroyed. The glasses are then wiped by hand. Public opinion should demand that these measures become law, as they are certainly as important as the inspection of food, which is considered quite natural in these days.

## Accidents in U. S. and England

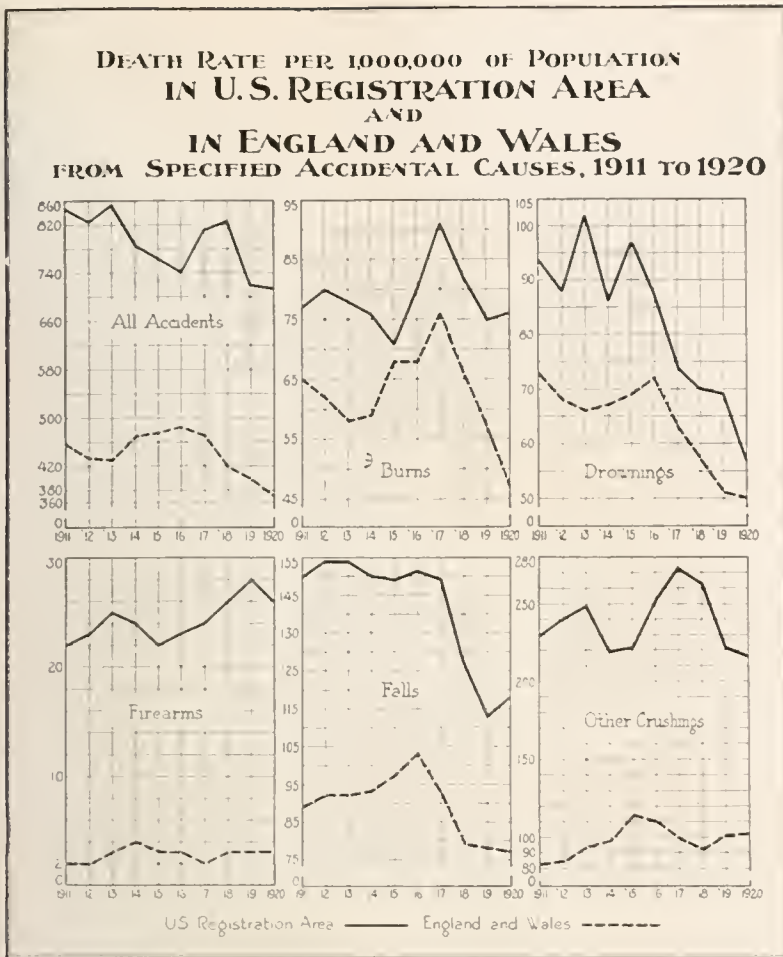

SEVENTY-SIX thousand accidental deaths is the astounding bill charged against America during 1920, according to the report of the public accident statistics committee of the National Safety Council presented at the Eleventh Annual Safety Congress which opened at Detroit, August 28.

Automobile accidents are held to be in part responsible for the unfavorable experience of 1920; in that year there were 1,200 more deaths from that cause than occurred in 1919. The chief reason for this, it is pointed out, was the large increase in the number of automobile users. The automobile fatality frequency for 1920 was 30 deaths a day, a total for the year of 11,000. The 1921 estimate of auto deaths, based on figures now available from 50 of the largest cities, indicates a considerable increase over 1920. General traffic accidents in 1921, however, will show a 5 per cent decrease over 1920, it is believed.

People died from falling accidents of all kinds at the rate of 34 a day, a higher rate than even automobiles. Burns claimed 22 lives a day, a total for the year of 8,088 and an increase of 215 over 1919. Other major causes of accidental deaths are listed in order of importance as follows: railroad accidents, 7,769; drownings, 6,066; deaths from gasing, 3,618; firearms, 2,767; mine accidents, 2,660; machinery, 2,660; street cars, 2,128; other vehicles, 2,022; conflagrations, 1,277. Other general causes of death are crushing accidents, poisonings, sharp instruments, excessive heat or cold, injuries by animals, lightning, and electricity.

The burden of accident mortality continues to fall chiefly upon children and upon the active working classes, according to the report which is the result of exhaustive research and statistical work on the part of the committee composed of Louis I. Dublin, chairman and chief statistician of the Metropolitan Life Insurance Com-

lic information on how accidents occur, and where and under what conditions they happen.

In commenting on the serious aspect of this continued life wastage through suppressible hazards, the report points out that had the American nation exercised the same regard for the life of the citizenry evidenced in England and Wales in 1920, there would have been 37,000 fewer lives lost in the United States. The death rate in England for 1911 to 1920 was 369 accidental fatalities for each million of population; in the United States the rate for the same period was 714, an uncontrovertible indictment in cold numbers of a national conscience which annually permits the killing and maiming of thousands through preventable accidents.

### Putting North Dakota on the Public Health Map

Realizing the inadequacy of the present State health organization in North Dakota, Dr. H. E. French, Secretary of the State Board of Health, recently requested assistance of the United States Public Health Service in placing the public health work upon a more substantial basis. As a result of this request, Surgeon Robert Olesen, who has been associated with the Wisconsin State Board of Health during the past three years, has been detailed for duty in North Dakota, with headquarters in Grand Forks.

Several years ago, when Chapin of Providence rated the efficiency of the state health departments, North Dakota ranked thirty-third among the states. Approximately one-half of the points allotted to the department at that time were available because of the efficiency of the laboratory of hygiene, thus making the actual standing of the department among the lowest in the entire Nation.

In 1914 Surgeon Carrol Fox of the United States Public Health Service made a comprehensive and exhaustive report upon the health needs of the state of North Dakota. This report was published and given wide circulation. A survey was likewise made of the public health situation and certain definite conclusions reached concerning the state health needs as a basis of securing the legislation necessary to make the plans a reality.

According to Dr. Olesen's report to the Surgeon General, the annual appropriation of the North Dakota State Board of Health is \$3,450, a sum barely sufficient to pay for the services of one fulltime clerk, make an effort at compiling the meager vital statistics, and publish a quarterly bul-

pany, Herbert P. Stellwagen, National Bureau of Casualty and Surety Underwriters, A. W. Koehler, New York Electric Railways, and E. W. Kopf.

Fatal accidents to children under five years number 9,880 or 13 per cent of the total. Young people from 15 to 24 bore 14 per cent of the burden; those from 25 to 34, 13 per cent; 35 to 44, 12 per cent, and those from 45 to 54, 10 per cent of all the accidental deaths of the year. A majority of the children came to their deaths through fatal burns, deleterious gases, and automobile accidents. One-third of all automobile deaths occur among children under 15 years of age.

Accidents in industry show a general decline of 1.3 deaths per 100,000 population for each year of the ten year period while public accidents decreased 1.1 per 100,000. The 1920 report shows public accidents on a slight upward turn while industrial accidents declined, this in spite of increased manufacturing activities. This is said to be due to the aggressive spirit shown by industry as a whole in organizing for safer working

conditions. Total industrial fatalities in 1920 were set at 12,500. The 1921 total, so far as can be anticipated from figures collected from insurance companies and other agencies, will probably be still lower because of the falling off in employment.

Over twice as many men died accidentally in 1920 as did women, the figures showing in round numbers 55,000 male fatalities as compared with 21,000 women. The latter, however, suffered greatly from domestic hazards, 6,000 having died from falls and 4,800 from burns; 2,756 died from injuries received in automobile accidents. Auto accidents were responsible for 8,300 deaths among men while railroad mishaps caused 6,930 fatalities.

A comprehensive means of collecting the information which will bring home to the American people the plain facts on the prevalence of certain kinds of accidents is included in the committee's report. Standard forms have been prepared for use in reporting all public accidents. These are to be distributed by the National Safety Council to every public accident official in the United States. In many cities these forms are already being used by the police and safety departments and are of great use in bringing to the attention of the pub-

letin. North Dakota is not in the registration area for births or deaths.

Public health work in North Dakota is, of course, not entirely lacking. In fact, some excellent efforts are being put forth by uncorrelated agencies having headquarters in different parts of the State. Unfortunately, however, these agencies are only nominally or not at all linked up with the State Board of Health. For example, the county public health nurses are supervised by the Red Cross and the majority of these workers are paid by Red Cross funds. The laboratory workers are under the supervision of the University of North Dakota. With the exception of these there is not a single full time public health worker even nominally associated with the State Board of Health.

As a result of a careful survey of the situation a plan has been devised whereby the various independent health agencies and funds may be amalgamated. In place of the present three-man State Board of Health chosen by the governor it is proposed to establish a seven-member board which shall appoint a trained, full-time state health officer. While the members of this board will be appointed by the governor, the terms of office will be for varying periods, thereby preventing to a large extent political domination. It is also proposed to make legal provision for the inclusion of at least two women on the board.

In addition to the highly important changes already outlined it is proposed to establish the simplest state health department commensurate with the needs. The plan suggested makes provision for four divisions in the department, each with a trained, full-time head. These divisions are: (1), Vital statistics; (2), preventable diseases; (3), child hygiene and public health nursing; and (4), sanitary engineering.

Through the expenditure of approximately eleven thousand dollars more than is now being appropriated to uncorrelated agencies, it will be possible to create an efficient department with seven full time supervisors and at least five full time clerks. In this estimate ample provision has been made for printing, traveling, and other incidental expenses. The total sum involved, \$43,500 is slightly over 1 per cent of the total funds appropriated by the state for all purposes and represents a *per capita* expenditure of \$0.067. In this connection it will be recalled that an expenditure of 2 per cent of the total funds is ordinarily

considered reasonable for public health purposes.

With a tangible plan available it now becomes necessary to arouse the people of the state to the desirability of acquiring a health organization which will actually prevent unnecessary sickness and premature death. To achieve this result the use of broad publicity among all classes will be required. Plans are being shaped to this end. There is ample reason to believe that as soon as the people of North Dakota adequately realize the necessity for competent health supervision they will demand an organization worthy of the state's fair name.

### States Pass New Laws Regarding Nurses

Nursing legislation has been enacted or considered in several of the states the past year. In New York, the law relating to registration of nurses was amended by extending until January 1, 1923, the period under which nurses could apply for license to practice as registered nurses under

waiver, and also extending until September 1, 1922 the date of waiver for attendants. This was done in order to accommodate many nurses who had not already taken advantage of the law, and who could only do so under an extension of it. Maryland passed laws requiring the registration of practical nurses and giving credit to nurses for training received in schools of public health. Massachusetts has passed an amendment to the school medical inspection law, by which suspicious cases among school children are referred to the school nurse or physician. A bill to increase compensation of the chairman of the Board of Registration in this state was defeated. In Virginia, a law adding a clinic of doctors and nurses to the Bureau of Tuberculosis Education of the State Board of Health was passed. A bill authorizing the State Department of Health to employ tuberculosis nurses was introduced in New Jersey, but not passed. There were no changes in nurse registration laws in Kentucky, Mississippi, or South Carolina.

## Vitamins in Canned Foods

CANNED foods supply vitamins as abundantly as the same foods cooked in the ordinary way is the fact disclosed by research carried on by Dr. E. F. Kohman of the Research Laboratory of the National Canners Association, Washington, D. C. The vitamin content is the greatest when foods are at the proper stage of maturity for consumption and decreases when the foods are held for a period of time. The fact that canned foods are prepared in their prime and must be in this condition for canning is in favor of the canned product.

Canned tomatoes are said to be among the richest sources of all vitamins in any product. On the strength of their content of the antiscorbutic vitamin, canned tomatoes have been recommended by physicians to supplement pasteurized milk in infant feeding. Special use was also made of canned tomatoes in army rations because of the vitamins in them. Canned tomatoes have been stored for three years and still found to be apparently as rich as ever in vitamins. This is longer than the antiscorbutic vitamin, which is the least stable of them all, can be kept by any other known method.

Canned foods are processed in vac-

uum while foods cooked on the stove are exposed to the air, which is the cause of a considerable loss of vitamin C. From the experimental evidences now available, canned foods are found to be practically as rich in vitamin A and B as the corresponding fresh raw products. In acid products, such as tomatoes and fruits, there is only a negligible destruction of vitamin C by ordinary cooking or in the canning process.

"No one should infer that raw fresh foods should be dispensed with in the normal human dietary," says Dr. Kohman. "This would be contrary to the universal belief among physiologists and students of nutrition. Those foods which can be eaten raw should always be so eaten as far as possible, when they can be obtained in the fresh state, at reasonable cost. When they are out of season, inconvenient, or uneconomical, their place can well be taken by canned products, as evidence shows that canned foods are as nutritious as ordinary cooked foods.

"A consideration of all the recent experimental evidence convinces one that it is possible to select a diet, entirely of canned foods, which is complete and adequate for long continued nutrition and which contains all the known vitamins."

# Digest of Sanitary and Hygienic Advance

**O**RGANIC disease of the heart occupies first place among the causes of death in the general population in the registration area of the United States: From 10 per cent to 15 per cent of all life insurance claims are for deaths from this cause, from 2 per cent to 3 per cent of all persons who apply for life insurance are rejected on account of cardiac abnormalities; during the world war 2½ per cent of the draftees were rejected on account of heart disease. Is it not about time for the sanitarians of the country to make a more direct and continuous attack upon the heart disease problem?

## London Medical Officers Study Cardiac Child

The cardiac child occupied the attention of the meeting which was held by the Medical Officers of Schools at London on June 26 last and Langmead (*The Lancet*, cciii, p. 18, July 1-22) stated that in schools the amount of recognizable cardiac disease was greater than the amount of tuberculosis therein. Placing the proportion at 3 per cent, it would mean that in England alone there are 183,000 cardiac children among the school population. One-third of the children attending schools for the physically defective are cardiac cases. Rheumatic fever is considered to be the overwhelming method of production of this condition, and the greater portal of entry of the infection is in all probability the upper air passages, particularly the tonsils and the nasopharynx. The eradication of adenoids and infected tonsils seems, therefore, to be at once the most available and logical method of attack. The careful, periodical physical examination of school children will do much to discover those who are in the early stages of cardiac disease and the conditions which predispose to it. This makes it possible to apply prophylactic measures, particularly those of naso-pharyngeal hygiene. It permits the regulation of the child's life in such a manner as to favor cure or compensation of his heart condition. To be sure, the cardiac child, if crippled at all, is crippled permanently and the question therefore resolves itself in such cases into the education of the child so that he may pursue a useful life in spite of his handicap. It is better, though, that the creation of cardiac children be prevented alto-

gether rather than that they shall be salvaged.

## Anti-diphtheritic Vaccination

Renault and Levy (*Le Prog. Med.*, p. 238, May 20-22) report a method of anti-diphtheritic vaccination which they have employed for more than a year. In searching for a more simple method than that of Park and Zinser, they employed a mixture consisting of 50 toxic and 50 antitoxic units (i. e., capable of neutralizing 5,000 toxic units). They make three subcutaneous injections of 1.5 c.c. of this mixture at weekly intervals. The authors hope to be able to reduce the number of injections to two or even one. The reactions are feeble. The results were controlled by the Schick reaction and an active immunity was found to be slowly produced.

## Open Air Schools for the Tropics

The essential feature of comfort in the tropics is air movement. Protection from light and weather are secondary to this, because if there is a free circulation of air, one may work and live in relative bodily comfort. This is particularly true of school houses in which turbulent young minds are cooped very much against their wills and in which productive study cannot be achieved in the presence of physical discomfort. Yet the great majority of schools in the tropics are badly ventilated and badly over-lighted for the reason that they are laid out on plans which with the addition of a heating plant might serve for Iceland itself. Some schools are not only uncomfortable and unhygienic, since they are merely reservoirs of dead, humid air which exercises a very deleterious effect upon the health and morale of the pupils but also they are extravagantly expensive. Too frequently the architects of the temperate zone relegate to themselves a superiority which is not existent and refuse to adopt designs which long generations of tropical dwellers have evolved out of their experience, or they modify tropical designs without intelligence and produce such effects as the bastard-Spanish or so-called "mission style." A simple shed having a double roof with a central cowl, a crowned concrete floor, one solid wall which the pupils face and screen walls with a two-foot clearance above

and below, is comfortable and hygienic. It is easily cleaned with a hose and is very cheap to construct. The material of choice for the walls is concrete, since it is fungus and ant-resistant, and the roof may be tile or composition. A thatch roof is cool but not durable and will harbor rodents. The outside roof should extend far enough to intercept the average rain from passing over the top of the screen wall.

## Tetra-chlorid in Hookworm Treatment

The value in the treatment of hookworms and ascarids is set forth by Leach (*A. M. A. Jour.* Vol. 78, 23, p. 1789) who states that chemically pure carbon tetra-chlorid administered to man in 10 c.c. doses produces no ill effects and that 12 c.c. removes all hookworms and ascarids, although having little effect on trichurids and oxyurids. Further work on the part of this investigator will be directed toward the determination of the optimal dose. In the fourteen cases reported all become negative for hookworms. The maximal dose given was 1 c.c. per 5.5 kg., and the minimal 1 c.c. per 19.6 kg. Nichols and Hampton (*B. M. J.* 3209, p. 8, July 1-22) after treating a very considerable number of persons with carbon tetra-chlorid, conclude that it is an efficient anthelmintic remedy for hookworms which may be administered safely in doses of 10 to 20 minims to children of 3 or 4 years of age, even when they are seriously ill from various causes. "It aids the expulsion of *Ascaris lumbricoides*, if it is followed by a purgative, but it is not as effective as chenopodium in killing this worm. The drug does not seriously deteriorate on keeping. It is more valuable for campaigns against hookworm disease because patients do not object to its taste; it is not necessary to proceed or follow the administration of it by a purge; it is much cheaper than any other drug that has been used; it can be prepared in a high degree of purity and a chemically pure preparation should always be used; the person who is being treated can do his usual days work." The authors suggest that since chenopodium is soluble in carbon tetra-chlorid that a mixture of the former with the latter, in the proportion of one to four, should be useful in the treatment of *Ascaris lumbricoides*.

### Statistics of Cancer in the Aged

Roussy and Laroux (*Bul. de l'Assoc. Fran. pour l'etude du Cancer*, xi, 2, Feb. 22) state that out of 400 necropsies in persons over 60 years of age, 34 or 8½ per cent had cancer, 33 epithelioma and one sarcoma of the lung. It occurred more frequently in men than in women, 22 to 12 or 64 per cent as against 36 per cent. Death in the bulk of cases was due to an intercurrent infection.

### Herpes Zoster and Varicella

The discussion of the identity of these two diseases still continues, and while the clinical evidence is exceedingly interesting and highly suggestive, the prudent scientist will do well to withhold final acceptance of the theory until the virus of varicella has been isolated. According to Hallez (*Gaz. des Hôp.* 95, 44, p. 713, June 6-22), Landouzy, in 1883, stated that the symptomatic zonas or "bosteriform eruptions" occurring in the course of tuberculosis, general paralysis, tabes, diabetes, myelitis, and peripheral neuritis should not be confused with true herpes zoster, an acute, febrile, almost cyclical, possibly contagious disease possibly conferring immunity. According to Landouzy, herpes zoster is a general disease having a tendency to circumscribe itself upon the nervous system and to produce secondary cutaneous expressions. He added: "There is between zoster and the zosteriform eruptions all the distance which separates and all the difference which distinguishes a disease from a symptom. Von Bokay of Budapest (*Jahrb. f. Kinderheilk.*, 1919) in 1892 reported five cases which he had observed and which seemed to substantiate in a measure this conception and he asked if the unknown causal agent of varicella might not under certain conditions manifest itself in the form of herpes zoster. In 1909 and 1919, he reviewed the subject, publishing additional cases, twelve in all, of observations of zonas followed by varicella after an interval of several days in other patients. Tremoulières (*Toulouse Mcd.* 1909) and Le Feuvre (*B. M. J.* 1913) published additional cases. A. Netter, who in 1920 reported cases which he thought tended to support von Bokay's observations, stated before the Paris Academy of Medicine at its meeting of May 16, 1922 that he had studied eleven new cases which apparently offered additional support to the hypothesis of the identity of the two diseases. He expressed the opinion that in cases

of zoster the virus of varicella is probably localized in a small number of the spinal ganglia or in a limited area of the spinal cord, and it is this localization which causes the difference between the eruptions of zoster and chickenpox. The literature of the subject which is quite extensive is well summarized by Kraus (*N. Y. Med. Jour.* Aug. 3-21) who concludes that "at the present time enough instances of the coincidence of these diseases have occurred to make it more than likely that they have a common cause, at least when they appear within twenty-one days of each other." The entire question is of considerable importance to epidemiologists and sanitarians, since it involves a possible explanation of the way in which chicken-pox may be perpetuated and transmitted.

### Epidemic Encephalitis

Price (*Am. Jour. Med. Sc.*, clxiii, 6, p. 871) reports his clinical observations in seventy-eight cases of epidemic encephalitis with special reference to end results. Approximately three-fourths of the cases terminated fatally; 61 per cent of the remainder were left with persistent or permanent sequelae. Relapses were frequent even several months after apparent recovery. The character and intensity of the initial symptoms bore no relation to the prognosis. While the disease at the onset is frequently associated with naso-pharyngeal infection, the disease bears no direct relation to true influenza. Children and young adults withstand the infection better than those of middle or old age. Change in the abdominal reflexes is an important and frequent symptom. Epileptiform attacks may be the sole manifestation of the infection. The curve of seasonal incidence in this group of cases rose in the late autumn, reached its maximum in mid-winter, and declined in the spring.

### Seriousness of Gonorrhoea in Women

This is well illustrated by Langstroth's conclusions (*N. Y. Med. J.* cxvi, p. 26 et seq. July 5-22. "Gonorrhoea in women is not confined to any one stratum of society and is increasing in frequency. The gravity of this disease is not appreciated as fully as it should be. The diagnosis is often difficult and is frequently confused with chronic non-specific infections of the cervical mucosa. Gonorrhoeal infection of the cervix is always followed by secondary infections which are often the cause of severe

systemic and mental disturbances. Surgical removal of Skene's glands and Bartholin's glands and the cervical endometrium is the only way in which the disease can be eradicated in the majority of cases."

"*Dans les Épidémies, bénignes ou dangereuses, il ne s'agit pas d'un homme, mais de la cité, et même de tout un pays.*"

### The Serum Treatment of Anthrax Septicemia

Symmers (*Annal. Surg.* lxxv, 6, p. 663 et seq. June-22) believes that it is time to revise our conceptions regarding the treatment of human anthrax. He is of the opinion that every anthrax lesion should be regarded as attended by general infection until proven to the contrary. Tampering with the pustule is unjustifiable. The only permissible form of local treatment is the isolation of the pustule within a barrier of anti-anthrax serum subcutaneously injected every four hours. A sterilizing dose of 150 to 200 c.c. of serum should be injected intravenously at once and supplemented by subsequent intravenous injections of 40 c.c. every four to eight hours. If the blood culture is negative at the end of twenty-four hours, the intravenous use of serum may be discontinued, the local injections being continued until the pus is free from anthrax bacilli, or at least until involution forms occur in the stained films. The liberal use of anti-anthrax serum if begun in time in anthrax septicemia is capable of sterilizing the blood rapidly.

### Indications for Quinin Intravenously

It should not be forgotten that the intravenous injection of the salts of quinin is not wholly without danger. Circulatory depression and certain nervous phenomena are frequently observed and local necrosis and sloughing occur once in a while. The dangers are, to a certain extent, offset by the rapidity and certainty with which the drug administered in this way establishes contact with the parasites of malaria. In cases in which on account of gastro-intestinal disturbance, there is a likelihood of non-absorption, or in which there is a grave condition such as delirium or coma, the intravenous route should be used, but it never should be a routine method of giving quinin and it is seldom indicated in the simple or chronic infections. When the intravenous

method is employed, all the precautions which surround the administration of salvarsan should be observed.

### The Treatment of Pediculosis by Pyrethrum Soap

Juilet, Galavielle and Margaret reported to the Society of Medical and Biological Sciences of Montpellier and the Mediterranean Languedoc (*Gaz. des Hop.* 95, 41, May 27-22) on the results obtained by them in the treatment of pediculosis with a soap prepared from the active oleo-resin of pyrethrum flowers, *Pyrethrum cinerariifolium*. After a single application the lice were killed immediately and the nits became dull and opaque and did not subsequently develop.

### Fetal Malformations and Syphilis

Henrotay (*Gynec. et Obst.* 1922, Vol. 4) reports the case of two sisters-in-law. One was delivered successfully of macerated fetuses and still-born children, two living children, and a child suffering with pemphigus and latter developing congenital syphilis. The other sister was delivered of an anencephalic monster. The two husbands (who were brothers) and their brother were all found to have hereditary syphilis. The author quotes also cases of a visceral ectopia with double talipes and spinabifida, a cephalocele with meningocele, a hydatiform mole, a hare-lip and cleft palate, all from mothers giving the serological reactions of syphilis. He is of the opinion that syphilis is a common cause of fetal malformations.

### Industrial Dermatoses

The frequency of dermatitis of the hands and forearms in workers in cutting oils and greases is emphasized by McLachlan (*Glasgow Med. Jour.*, Apr.-22). Carefully sulphonated compounds or those made of good potash or soda soaps or of petroleum seem free of danger. These oily mixtures and pastes are used in mixtures with water for cooling, lubricating, producing smooth finishes and also for protecting metals against oxidation or corrosion. The dermatitis, which occurs in three types, seems to depend upon the frequent wetting of the skin with the watery fluid which is irritant by reason of containing free alkalis, fatty acids, metallic chips, particularly those of copper, or impure anthracene oil. Prophylaxis is best accomplished by the use of pure high-grade cutting oils and by careful personal cleanliness.

### Preventive Obstetrics Assuming Greater Importance

Preventive obstetrics is a phase of sanitary medicine which is gradually assuming greater importance, although in America it has not yet received the widespread attention which it deserves. The British Ministry of Health has long realized the vital necessity of study of the subject and has issued a report (*Min. Of. Health Rpts.*, 7, 'On the Causation of Fetal Death, Eardley, Holland) which is commended to those interested in the subject and to those health workers who care to consider public medicine in its broadest phases. Out of 300 fetuses from mixed districts studied by him, Mr. Holland found that 51 per cent of the deaths were due to complications of labor, 16 per cent to syphilis, 10 per cent to the toxemias of pregnancy, 2 per cent to chronic renal and other maternal diseases, 6 per cent to relative placental insufficiency, 5 per cent to fetal deformity and that in the remainder, (10 per cent) the cause of death was undetermined. He expresses the opinion that more fetuses were killed by the complications of labor than died during pregnancy from maternal or placental disease and estimates that half of these children might have been saved, 20 per cent by adequate antenatal care, an equal proportion by improved obstetrical technic, and the remainder by a combination of both methods.

### Mode of Infection and Prophylaxis of Leprosy

Sir Leonard Rogers, (*B. M. J.*, 3208, June 24, 1922, p. 987 et seq.) analyses the probable source of the infection in 700 recorded cases of leprosy as follows:

Mode of Infection	Number	Percentage
Conjugal	85	12.14
Cohabiting	43	6.13
House	180	25.7
Room	35	5.0
Bed	64	9.14
Attending on lepers	139	19.87
Leper playmate	23	3.28
Close association with leper	113	16.14
Wet nurse	8	1.14
Wearing leper's clothes	3	0.43
Vaccination	4	0.59
Inoculation from leper	3	0.43

### Relation of Food to Alimentary Toxemia

Intestinal toxemia, whether from intestinal stasis, food fermentation, or poisonous derivatives from toxic microbes has a most important bearing upon nervous exhaustion. The whole subject is discussed by Theodore Thompson, M. D., in a recent issue of *The Lancet*. The possibility that the alimentary tract is the site of infection in certain of the acute disease of the brain has received striking confirmation in recent work upon cerebrospinal fever, and some of the most hopeful results have been obtained in acute mental conditions by clearing up all possible foci of infection.

Likewise in cases of nervous exhaustion the existence of bodily poisons needs always to be excluded. To prevent the nervous complications of intestinal stasis it is most important of all to attend to the hygiene of the mouth and associated cavities. Regular daily evacuation of the bowels is essential. The relation of food to alimentary toxemia is very important. Dr. Thompson quotes the work of Coombes and others as having shown that the ingestion of large quantities of meat tends to produce excessive fermentation in the intestine. The observers advise in such cases a period of rest from meat foods for some weeks and the giving of farinaceous foods during this period. On the other hand, many observers have shown that the ingestion of carbohydrates, especially sugar, favors certain forms of intestinal putrefaction. The excessive use of sugar in the coffee materially delays the emptying of the stomach. It is probable that diminution in the total amount of food is of the most value in reducing alimentary toxemia. Most people eat far too much and might with advantage make a very considerable diminution in the total amount of food eaten. The preparation of foods is also most important; all salads and uncooked vegetables should be carefully prepared before being eaten. Especially should the utmost endeavors be made to protect the source of the milk supply.

The New York Reconstruction Hospital now has a night clinic for the treatment of workers who still require after-care to remove remnants of disability. This allows the man to work during the day. The clinic is open three nights a week from 7 to 9 o'clock.

## Civil Servant or Parasite

IT is the fashion in certain political circles in these days of excessive taxation to assume that the employees of the government constitute a largely useless burden upon the resources of the community. In a sense this is perhaps an enlightening revelation of the politician's attitude toward the "jobs" which he often has assumed the right to dispense. To the faithful civil servant who has been inclined to believe that he was earning his salt and sometimes a good bit more, the following editorial from the *New York Times* of August 6 will come as a gratifying recognition of the real state of the case:

Senator Stanley pictures a "tax-eater" on the back of every two "tax-producers." He is not very sure about his statistics. He states merely that "It has been said" that there are fifteen millions of them. The implication is that they do nothing but devour as parasites what the others produce. While this may be true of some public officials, it is a too hasty generalization. An officeholder may be one of the most productive of all men. Many of even the "unknown experts" are doing a part of the tax-producers' work, and so lightening his burden.

They may be thought of as fighters: men fighting fires in the forests and tenements; men and women fighting-pathogenic bacteria in the air, earth, and water; fighting flood, and drought, heat, and cold; fighting ignorance and sloth and passion in thousands of schools; fighting uncleanness, disease, and waste with broom and lens and test-tube and scalpel and honest and expert eyes and skillful hands.

"The Third Man" is the sweeper of city streets and the "pathmaster" of the country roads. He gathers our letters of affection and business and distributes them even in the remotest cabins on the mountains and plains. He weighs the winds, reads the portents of the clouds, makes predictions of fair and foul weather. He pasteurizes the milk, tests and labels foods and drugs, corrects false balances and short measure, keeps watch over forest and stream, and gives warning of rocks and

shoals to men at sea and of plague and poison to those on land. He is warden of fish, bird and wild beast, host to the homeless, guardian to the child who comes friendless into this world and chaplain to the man who goes friendless out of it. He is assessor and collector, treasurer and controller, teacher of twenty millions of children, youth, men and women, public librarian, superintendent, doctor, nurse and guard in public hospital, prison, almshouse, coroner and keeper of the potter's field, Governor, Mayor, Judge, prosecuting attorney, sheriff, soldier, sailor, General, Admiral, legislator, Chief Justice, member of the Cabinet, President.

## Pyrotechnics and Performance

WHAT'S the matter?, said the Old Doctor to the Health Officer.

"I'm feeling rather low in my alleged mind," said the Health Officer.

"*Et pourquoi?*" said the O.D., who had served in France and loved to pose as bi-lingual.

"The County Supervisors turned me down. I asked for a thousand dollars to drain that swamp west of town, the worst Anopheles breeder in the county. Said they couldn't afford it because they had to put up fifteen hundred for Fourth of July fireworks. Great Scott!! Fifteen hundred dollars to burn up in an hour and all I wanted was a thousand for sub-soil drainage which would have been protecting this town for the next century. I'm about ready to quit and transfer my laudable activities to some less benighted community."

"Well, I wouldn't take it so hard, if I were you," replied the O.D. "You've badgered 'em into a new filtration plant. You've got in a sewer system for most all the town, and your privy ordinance covers the rest. You've started the medical inspection of schools and you have a visiting nurse. You've reduced the death rate slightly—or at least you think you have—and your ante-natal work is getting started splendidly—"

"Yes, I know, but if I could do this piece of drainage, I could reduce malaria in this town 30 per cent!"

"Sure, you could, and you'll get that work done yet. You're a persistent young man, all right. But what you've got to remember is that the dear old public which is paying the bills likes something shown for its money. Didn't it contribute freely to erect a tablet to old Hi Transom who was the first settler of this town, a no-account ruffian with the disposition of a barbed wire fence crossed in love? Sure they did. Why? It made a show. That's why you got your money for the Swat-The-Fly campaign which you know was all foolishness when every stable in this town was breeding flies faster than all the swatters could swat 'em. That's how you got away with your Better-Baby-Week which worried a lot of healthy babies so that we O.D.'s had our hands full for a month afterwards. The public wants a brass band, a silver tongued

orator, silk badges and a brand new sensation every time it parts with a nickel."

"But it'll reduce the mosquitoes if I get that subsoil drainage. The young fellows can sit with the girls behind the honey suckles on the front porch on summer evenings and put in their time to better advantage than in slapping blood thirsty *Taoniorynchi* and *Anophelinae*."

"Sure they can. Why don't you get up an Anti-Anopheles-Week? Get the Rotary Club to dig the first ditch and put in the first tile. Have a race between our two Boy Scout Patrols as to which can dig the most ditch in an hour. Have the Women's Clubs serve coffee to the workers, while the Silver Cornet Band furnishes the music, and our own corn-fed congressman supplies the words. Give the people a grand old Roman holiday and after they've messed around in the swamp for a while go back after the Supervisors. They'll have to come through because you'll have public opinion behind you."

"Well that looks pretty good to me."

"Sure it does! If you'd been curing afterpains with a beautiful red mixture of *syrupus rubi* and dilute hydrochloric acid as long as I have you'd know more about the general public."

---

## Accident Prevention as a Municipal Health Problem

ATTENTION has been called in previous issues of *THE NATION'S HEALTH* to the importance of accidents as a factor in the preventable death rate. There is no group of causes of death so readily amenable to control and yet health officials at least have almost wholly ignored this problem in favor of far less promising although more traditional lines of endeavor. Dr. L. I. Dublin estimates that in 1920 over 75,000 lives were lost as a result of so-called "accidents" in the United States, the rate per 100,000 population (71.4) being generally comparable with the death rates from such causes as congenital debility, nephritis and Bright's disease, cerebral hemorrhage and softening of the brain, and cancer and other malignant tumors, and in marked excess of the rate for diarrhea of infants under two years of age. This accident rate for the United States is nearly double that reported for England.

During the last few years it seems that the public is at last being awakened to the importance of controlling the accident hazard. An attack on this problem on a broad municipal scale was first made in St. Louis in 1918 under the leadership of Mr. C. W. Price of the National Safety Council. A municipal safety week was organized

in spectacular fashion with the result that but one fatal accident occurred during the week as compared with a normal of 24 of such deaths for a corresponding seven day period. Nor was the effect a purely transient one. The annual total of accidental deaths for St. Louis fell steadily from 510 in 1917 to 330 in 1921, the rate for deaths due to motor vehicles fell from 3.7 per 1,000 cars in 1919 to 1.4 in 1921, and the number of deaths of school children fell from 49 in 1919 to 18 in 1921. Similar results were obtained in Milwaukee, Detroit, and other cities. In Detroit, for example, the deaths of children of school age due to accidents fell from 96 in 1919 to 30 in 1921. These accidental deaths of children carry such a peculiar appeal that in Baltimore last June the most dramatic feature of Safety Week was the formal dedication by the Mayor of a monument "in memory of the 130 children whose lives were sacrificed by accident during the year 1921." During this Safety Week in Baltimore there were but two accidental deaths as compared with a normal of nine.

The most ambitious municipal Safety campaign yet conceived is to be initiated by a Safety Week beginning October 8 to be held in New York City under the primary auspices of the Safety Institute of America and under the active direction of Mr. C. W. Price, who organized the movement in the cities mentioned above. The week will be only the beginning of a program for cultivating safety habits throughout the year in which the public schools will play a central part. Judge Elbert H. Gary whose contributions to the cause of industrial safety have been so notable in the past has accepted the chairmanship of the General Committee which will be in charge of the campaign.

Mr. L. V. Coleman, director of the Safety Institute, in commenting on the organization of this committee, points out that while industrial accidents have decreased 20 per cent in New York City in the past three years, accidents to children have increased 22 per cent. He continues:

The Police Commissioner predicts that 550 children of 13 years or under will be killed in highway accidents in New York City during the current year, and the Safety Institute's survey during June disclosed the fact that 113 children were killed in that one month.

Judge Gary's decision to accept the leadership of the New York Public Safety Campaign came as the result of a personal study of the accident situation in New York City and of what had been accomplished in other cities through carefully organized, permanent safety campaigns. His decision was largely influenced by the consideration that this movement, now developing in New York, may offer him the opportunity to render even a greater service to humanity than he rendered by his pioneer efforts in industrial safety.

Judge Gary's acceptance of the leadership of this enterprise marks more than the beginning of a public safety week campaign. It signals even more than the launching of a permanent program to reduce the acci-

dent toll in New York City. The real significance of the acceptance is national for it marks the crystallization of a movement which has been in solution, so to speak, for the ten years since its inception.

Recognition of the public safety movement by Judge Gary through his assumption of formal and active leadership raises the movement to first rank and assures it a place in the country's history. It places public safety on a firm foundation besides the achievement of industry in the prevention of industrial accidents.

New York's Safety Campaign will indeed be watched with eager interest and cannot fail to exercise a power influence upon the spread of this movement. It deserves the earnest support of all public health workers. Our aim is to prevent preventable disability and death; and the control of the accident hazard is one of the most effective ways of accomplishing this end.

---

### Death of Robert Bruce Low

AMERICAN sanitarians who had had the privilege of knowing the kindly author of "The Progress and Diffusion of Plague, Cholera and Yellow Fever Throughout the World" learned with regret of the death of Dr. Robert Bruce Low recently in the seventy-seventh year of his life. Many who were in London during the World War will remember the gentle doctor at the Local Government Board office who was never too busy to lead his American visitors through the mazes of the health system of the United Kingdom, to discuss with the greatest erudition the most recent advances in epidemiology, yet who always modestly referred to himself as "an old comb-out." Never hurried yet always busy, always looking as though he had just stepped from a bandbox, always charming, kindly, and gentle, and always giving from his vast store of experience, a man greatly to be envied in his quiet poise, his unassuming dignity, a perfect example of how best to grow old. In his passing, sanitary science has lost an historical figure and a tireless worker, and a host of health officers all over the world have lost a valued friend.

Born in Edinburgh in 1846, graduated in medicine in 1867, a rural practitioner for the succeeding nineteen years, he became a Medical Inspector of the Local Government Board in 1887. He arrived at his new post with a wide field experience growing out of his work as a rural medical officer of health, a district medical officer, a public vaccinator, a work-house medical officer, the Surgeon-Major of the Second Volunteer Battalion, Yorkshire Regiment, and with the D.P.H. degree conferred by Cambridge in 1879. In 1886 he published an article on the tenure of office and the method of appointment of Medical Officers of Health which played a great part in securing for these officers better terms of appointment.

In his labors with the Local Government Board he played an integral part in the upbuilding of the United Kingdom and his published reports, many of which were almost epoch making, cover a wide range of epidemiological subjects. His work as examiner in sanitary science, state medicine, and public health at the Universities of Edinburgh, Glasgow, Leeds, and Cambridge gave him a wonderful opportunity to insist on proper qualifications for those intending to enter into public health work. In 1919 he was appointed by the General Medical Council, Inspector of Examinations of the twenty-two examining bodies that grant degrees and diplomas in public health and sanitary science in the United Kingdom and Ireland, thus giving him an added opportunity to further standardize the profession of sanitary medicine, and it was in this office that his useful, praiseworthy life closed.

---

### Personnel in Preventive Medicine

THE field of public health work engages the full time of something like ten thousand trained workers, and numbers in its personnel such specialized functionaries as sanitary engineers, laboratory directors, specialists in statistics, epidemiologists, administrators of clinics, mental hygienists and psychologists, nutritional experts, and highly scientific hygienists, but is not as yet, according to Dr. George E. Vincent, president of the Rockefeller Foundation, so organized in its standards or objectives as to attract widely the class of workers the service demands. Curative rather than preventive medicine, has commanded the pick of men in training. This is not justified by the opportunities open in the public health field, and 20,000 persons must be recruited to the public health field in the next ten years to take care of the increasing demands of preventive medicine. In the annual report of the Rockefeller Foundation, summing up the results of a survey made of students now enrolled in leading American medical schools with respect to their evaluation of a career in public health work as compared to the practice of curative medicine, Dr. Vincent says:

The reasons given by these young men for deciding against preventive medicine in preference to private practice are:

"It is not a socially recognized, clearly professionalized calling; there are no special schools for adequate training; tenure and promotion depend not on merit but political 'pull'; salaries are meager; the private practice of curative medicine is more reputable, independent, profitable and satisfying."

These young men are in many respects uninformed and misinformed. Preventive medicine has already gained the status of a profession and is making rapid progress in public favor. At least two special schools of high rank are offering a thorough and appropriate training. An increasing number of important posts are freeing them-

selves from the trammels of "spoils politics." The salary received by a health officer of full rank probably exceeds the income of the average private practitioner. Private practice has many disadvantages; excessive overtime and night work, poor collections, the necessity of dunning patients, little chance to study, constant economic pressure, a heavy burden of unpaid service, competition with quacks and charlatans, temptation to surrender scientific ideals. Public health service, on the other hand, is making a strong appeal to men and women of imagination, courage and social spirit just because it does not involve most of these things and offers many positive attractions.

Yet it must be admitted that the skeptical undergraduates are not wholly wrong. Public ignorance and indifference, invidious comparisons, lack of sound training in many officials, prejudice against law enforcement, delay the full appreciation of what preventive medicine means to society. The establishment of adequate schools has been a recent event. A few disheartening instances of political tampering with health departments have occurred of late. It is also true that the level of pay is far too low. Even the few highest salaries suffer painfully in comparison with the annual income of leading private consultants and surgeons. A greater share of popular admiration, larger freedom from control, close personal relations with appreciative individuals, a deeper sense of professional pride probably are still the portion of the practitioner of curative medicine. Persistent efforts then will be needed to make public health careers more attractive to the persons best fitted for successful work. Much can be done to enlighten and challenge medical students and young graduate doctors, but the problem calls for something far more fundamental than that. Only when people understand the purpose and methods of public health measures can they be counted upon to cooperate willingly and efficiently.

Many of the tenable objections to public health work as a professional career will give way before the wider program and increased opportunity for thorough education in this field. Several first rate schools are now preparing a body of health workers who will set new standards of service and make invalid the invidious comparisons which have sometimes been made in the past with some justice. Meanwhile, a new value of the service is seen as the demand for such workers increases.

### Seekers, Doers, Vulgarizers—The Triad in Public Health Work

THERE are three distinct types of men in the profession of sanitary medicine—the research worker, the practical sanitarian who applies the knowledge which the research worker has laboriously gained, and the vulgarizer\* who talks about the work of the other two. A combination of the latter two types is not uncommon, a union of the first two is seldom seen, of the first and last almost never and then looked upon with suspicion by a profession which at best is apt to be extremely critical of any departure from its accepted standards. Once in a long time an individual combines the traits of all three. Such an one is an intellectual giant, a tremendous force for good. All three types are necessary to the advancement of hygiene as a means of community salvation.

The research worker attacks a given problem

and solves it in all its minutiae. It may be a piece of pure science without any apparent application in a practical way and it may lie unused for years in the lumber-room of knowledge, until the discovery of some co-related fact renders it practical of application. Therefore, while the garnering of facts of no immediate value may at first glance appear wasteful, this is not the case, since no addition to the sum of human knowledge is useless. Also, the performance of research which apparently does not prove anything, is of value since negative findings assist the advancement of knowledge by a process of elimination and thus conserve the time and resources of other workers.

The seeker is essentially a man of detail and sometimes the very nature of his work narrows, rather than broadens, his mind. He is the personification of skepticism and he believes nothing which is not proved by the standards of cold reason. Strangely enough, his is a fertile imagination, perfectly controlled by a nature whose motive power is an insatiable scientific curiosity. He loves facts for themselves and the priority of finding them.

The doer is a rougher type, in a way more ruthless and possessed of a less creative imagination, yet at the same time his is a warmer and more sanguine nature than is that of the seeker. He cares for nothing which he cannot put to work but he is an optimist, willing to try any sort of measure which holds out the reasonable promise of success. He measures facts by what they will do and by what they will cost in doing. Facts are to him tools which may be put into the hands of an organized force for the protection of society. He cares not for details. His interest lies in results not in processes. He looks at his profession through broad-angle lenses rather than with a close-up, sharp focus. His energy devotes itself to making facts work for him rather in discovering them. The doer loves facts for what they will do.

The vulgarizer to a certain extent is a smatterer. His ability lies in an impressive exterior, a convincing manner, and an ability to divest a subject of all extraneous matter and to reduce it to the least common denominator of the vernacular. There is something of the histrionic in his make-up. He is, so to speak, the bard of sanitation. Absolute accuracy he does not demand; the pros and cons of a half-proved discovery do not interest him. He looks for the high lights, not the chiaroscuro. He has the quality of interesting people, of attracting their minds to the consideration of health. He is a popular educator, speaking the language of the layman to translate to him

\*Vulgarize: To diffuse among the common people." Standard Dictionary.

the facts of science, an evangelical sanitarian running ahead to preach the gospel of health and urging his hearers by word, by speech, by illustrations, to turn from a sinning against Hygeia and to seek the paths of sanitary living. He popularizes the work of the other two. He is the messenger of him who seeks and finds and of him who applies sanitary knowledge, bringing to the people in their own rude tongue tidings of great hope and joy. He is the creator of public opinion.

Yet all three are complementary to each other—all are necessary to the public health. Each working honestly carries forward the cause of sanitary medicine, the one to seek and find, the one to apply and the other to bring it all to the man in the street, the wife beside the cradle and the child in his school.

### Stephen Smith the Health Association Centenarian, Dies

**D**R. STEPHEN SMITH, pioneer in sanitary reforms, a founder of the American Public Health Association, and, more recently, an able advocate of the thesis that a man normally should round out one hundred years of life, died at Montour Falls, N. Y., August 26. He would have been one hundred years old if he had lived until February 19. His whole activity was in public health lines and his published books, "Who is Insane," depicting his experience as a lunacy commissioner, and "The City That Was," telling of conditions in New York before his sanitary reforms—are handbooks for public health workers.

Dr. Smith followed for the term of his natural life his own precept to "work and keep out of the easy chair," and his life work was one of rare public service. He initiated the campaign against the miserable sanitary conditions that characterized the New York of fifty years ago. Dr. Smith himself drafted the act creating the Board of Health and was the first administrator of its almost autocratic powers. The organization of the American Public Health Association was a logical extension of his campaign against preventable disease. The visible results of his activities are all the more remarkable because his work was instituted before sanitation became a science.

---

### Health Association in Fifty-first Annual Meeting

**T**HE fifty-first annual meeting of the American Public Health Association will be held in Cleveland, O., from October 16 to October 19. The Association headquarters are to be located at the Hotel Statler.

The various sections will offer programs covering the fields of public health administration, sanitary engineering, food and drugs, child hygiene, laboratories, industrial hygiene, and vital statistics. Tentative programs of these sections, appearing in the September issue of the *American Journal of Public Health*, indicate that the convention will be both interesting and instructive. Meetings will also be held by the provisional sections on Health Education and Publicity and Public Health Nursing.

Commercial exhibits, which always attract and interest convention visitors, are not to be omitted. Plans for this feature are already under way and contracts for considerable floor space are signed. The cooperative book-stall will be a new feature. The leading medical and general publishers of the country will unite in showing the recent and standard works covering the many fields which the interest of the health worker embraces.

The character of health work is such that, in the majority of cases, the workers contacts have a more or less definite geographical limitation. Association meetings and conventions offer to all an opportunity of broadening their circle of acquaintances and restimulating their interest in their chosen work.

---

**A**N INTERESTING health situation has developed in Chicago. Dr. Herman N. Bundeson, health officer, has taken the position that the social diseases under drastic methods are as amenable to control as any other communicable disease, and that his department will provide clinical units where diseased inmates of disorderly houses may (or must) receive consistent care, compulsory medical examination to determine the need of treatment. Placards placed by the Department of Health will indicate the houses which are foci of infection afford the essential incentive to clean up.

The opposition argues that for clinics to give to inmates of disorderly houses a clean bill of health would in effect cause the city health department to abet vice; that medical treatment cannot properly be forced upon any group of people; that additional health machinery means merely additional power for political manipulation. Public opinion is in the balance. Meanwhile, the public is gaining some basis of fact for the formation of public opinion. It must be conceded an anomaly to quarantine measles and ignore social diseases and already the public is alive to the fact that the work of a health department may be held to involve more than routine inspection and the keeping of records, or even putting up placards for chickenpox.

# HEALTH IN INDUSTRY

*Official Organ of the American Association of  
Industrial Physicians and Surgeons*

*Editors for the Association*

THOMAS CROWDER, M.D.

WADE WRIGHT, M.D.

*Officers of the Association*

C. E. FORD, M.D., *President*

C. F. N. SCHRAM, M.D., *Vice-President*

L. A. SHOUDY, M.D., *Second Vice-President*

W. A. SAWYER, M.D., *Secretary-Treas.*

## The Industrial Physician's Community Relations\*

INDUSTRIAL medical practice should logically be coordinated with the activities of non-industrial physicians and with those of community health agencies, all serving with the common purpose of advancing the public health. With little doubt much of the existent tendency of the medical profession to view with the skepticism or alarm the growth of industrial medicine will be overcome by a demonstration of the value of cooperation between industrial physicians and other groups engaged in health work.

The relations of the industrial physician with the private practitioner may usually be maintained harmoniously and helpfully when establishment medical practice is conducted with the full regard for reciprocal rights which prevails among ethical physicians in non-industrial practice. The industrial physician because of his opportunities for continued contact with workers is enabled to be of great assistance to private practitioners in securing early diagnoses, in the maintenance of treatment, and in the subsequent follow-up observation of patients.

It is the belief of this committee that it is not the reasonable and proper responsibility of an industrial physician to treat cases of serious or incapacitating illness of non-industrial origin, except under unusual cir-

cumstances, such as those incident to the geographic isolation of an industrial establishment or in connection with a medical service-plan supported financially in whole or in part by industrial workers. Minor disabilities of non-industrial origin, if not incapacitating, may well be treated in the plant dispensary to the material advantage of the workers and employers. Services of this nature should not be paid for by employees. It is not an uncommon practice among industrial physicians to augment their incomes from this source. The procedure tends toward exploitation of workers and is to be condemned.

The committee, further, is of the opinion that it is unwise for physicians in the employ of industrial establishments to accept fees from workers for attendance upon cases of incapacitating non-industrial illness or for surgical operations for non-industrial conditions in such cases, when circumstances are such in the community in which a plant may be located as to permit of the placement of patients under other satisfactory professional care. It is obvious that attendance upon cases of the nature outlined is essentially a function of the private practitioner and not of the industrial physician.

### Hospital Needs in Industry

There has not been displayed as yet, in most industrial communities, any notable tendency to adapt hospital organization to the medical and surgical needs of the industry. This is particularly true in regard to the hospitalization of cases falling within the scope of workmen's compensation legislation. Legal provisions limiting

the amounts payable for hospital care of such cases have frequently led hospital executives to oppose the ready admission of compensation cases.

It is desirable that industrial physicians maintain such close relations with local hospitals as may assure for the workers in the industrial establishments which such physicians represent adequate hospital care in the event of serious injury or illness. It is particularly to be desired that there be in industrial communities hospitals with "open staffs" under the administrative control necessary to maintain high standards, in which industrial physicians may care for industrial cases demanding hospitalization. Competent industrial surgeons are at the present time able to secure in many types of cases surgical results superior to those apparently obtainable by general surgeons in regard to both end results and periods of disability.

In most large cities there are dispensaries to which ambulatory cases may be referred for diagnosis and may, through such agencies, secure for workers special services which are beyond the range of industrial medical department activities. It is certain, however, that there is frequent abuse in the utilization of such diagnostic centers by industrial physicians. Undoubtedly many cases are referred to dispensaries which could be adequately handled in plant medical departments through a slightly greater medical diligence the plant physician thus avoiding needless time loss with its attendant costs.

There are in the country but few night clinics for industrial workers. There would be more if industrial

\*Report of the committee, consisting of Wade Wright, chairman, Robert S. Quinby, and W. Irving Clark, appointed to report to the meeting of the American Association of Industrial Physicians and Surgeons, May 22, 1922, on the following question: "Define the proper limitations of the industrial physician in relation to general community health activities as well as the extra industrial cases of illness or disability and to the work of the private practitioner, hospitals, community dispensaries, and diagnostic clinics."

physicians would in behalf of industry voice a demand for such service. Each visit to a night clinic may represent a day's work saved to an industrial organization.

Group diagnostic clinics prepared to render diagnostic service upon a moderate fee basis are being established in many medical centers. Industrial physicians and their patients may greatly benefit by access to clinics of this type, but it is the be-

lief of this committee that in most instances obscure cases of non-industrial origin appearing in industrial dispensaries should be referred directly to private practitioners who may then call upon such consultants or groups of consultants as may be required. There exists in many industrial communities numerous voluntary health agencies, such as district nursing associations, tuberculosis and venereal disease clinics and

bureaus for occupational therapy and vocational rehabilitation. Industrial physicians have in most such organizations valuable resources with which to supplement the diagnostic and therapeutic facilities available in industrial medical departments and appropriate use should be made of them.

Health work in industry is an intrinsic part of health work in the community.

## Need of Adequate Artificial Illumination\*

### Proper Lighting Means Protection and Improved Production to Industrial Workers

BY G. BERTRAM REGAR, ILLUMINATING ENGINEER, PHILADELPHIA ELECTRIC COMPANY, PHILADELPHIA, PA.

**A**RTIFICIAL lighting is a subject that is little understood in general, and still less appreciated. Perhaps no other achievement has added more to the progress of the world's accomplishments than has lighting. In prehistoric times, man's day was that of the sun; but with the control of fire, came light. Thus, artificial light came to be associated with safety, warmth, and pleasure. Its growth is closely allied with enlightenment and culture; and even at the present time, we find both missing in those parts of the world where lighting has not progressed. In fact, the torch is the emblem of progress. Today, the idea of artificial lighting is interwoven with thoughts of beauty in the home, success in commerce, safety in the streets, and efficiency in industry.

Lighting service, as a rule, has not reached the high standard attained by the power and appliance service. The plant engineer can readily determine the power necessary, and there is little complaint of its performance. The housewife would not give up the use of the many labor-saving devices. The lighting installation, however, is very frequently subject to the criticism that some other installation is better.

The Creator gave the sun and light, and there seems to be an instinctive group psychology against paying for light as a service. On the other hand, the average person will concede that man is entitled to considerable credit for manufacturing the power that makes possible the use

of a flat-iron or a vacuum cleaner. I am convinced, therefore, that it is not so much a matter of economy as it is one of a lack of appreciation of the great service which light can be made to perform. Its potentialities are perhaps greater than those of any other commodity; and its cost is only a small percentage of the general overhead expense of the home, the store, or the factory.

Lighting has three basic principles: (1) Utilization. Successful business methods demand that the lighting be good; and good lighting is efficient, because the predominating factors have been treated in a scientific way. (2) The physical effect. With the recognized advantages,

from the commercial and the industrial standpoint, of a higher intensity of illumination, if the eyes of our people and of future generations are to be conserved, then careful consideration must be given to the subject of proper direction, diffusion, and color of lighting. (3) The psychological effect. With the advancement of enlightenment, we have, naturally, been educated to the comforts and refinement of our present day lives; and the artistic effect of lighting, therefore, plays a prominent part as to whether it is pleasing or distasteful to the eye. It must, however, be borne in mind that the relationship of each of these to the other varies according to the class of installation;

Spinning mill having drop cords with bare lamps. The lighting is very poor and causes eye strain.

\*Read before the Fifteenth Conference of Pennsylvania Industrial Physicians and Surgeons at Harrisburg, Pa., May 25, 1922.

Same mill after changes were made, showing a splendid example of good lighting.

that is, whether home, store or factory.

Considering the subject from the utilization standpoint, it has only been in the past three or four years that lighting, in the minds of factory executives, has been taken out of the janitor-service class and placed where it belongs with automatic machinery and labor-saving devices. Manufacturers are beginning to realize that it is a substantial aid to production. The state authorities, recognizing that increased output and the protection of the limbs and eyesight of the working classes are a distinct economic gain to the state, are not slow to take advantage of its great potentialities and are adopting so-called factory or industrial-lighting codes.

In these state codes, intensities of lighting for various classes of operation are specified, depending upon the nature and fitness of the detail to be observed, the closeness of application required, and the color of the working surfaces. These intensities are intended only to protect the life and, to a reasonable extent, the eyesight of the operator.

Mr. E. E. Simpson of the Travelers' Insurance Company is authority for the statement that during the year 1919 there were more than two million industrial accidents causing loss of time. Of this number, twenty-five thousand were fatal. "There is some foundation for assuming that 18 per cent of our industrial accidents are due to the defects in lighting installations. On that basis, the services of one hundred and six thousand men for one year are lost annually because the illumination provided is not adequate for the safety of the workman. That this condition could

exist year after year is all the more reprehensible because of the fact that the remedy is so easily applied and has beneficial results in many ways other than the safety involved. Accidents caused by carelessness, inattention, or ignorance can be eliminated only by a long-continued, painstaking, educational campaign, often involving a change in long-established habits. Elimination of accidents due to inadequate or improper lighting is simply a matter of purchasing the proper equipment and installing it under competent direction. In fact, it seems proper to include illumination in the list of mechanical safeguards for the reason that the lamps and reflectors provide a guard. Illumination points out the hazards just as effectively as a railing points out the danger of and provides protection against the hazard of a revolving flywheel."

#### Industrial Lighting Survey

However, Government requirements for lighting are concerned only with protection, and have no bearing upon economical production which necessitates higher intensities than are required in the state codes.

The necessity for a more general use of artificial lighting, especially in the larger cities, has been brought about by the centralization of business, which has resulted in the increase of building heights, with a corresponding lessening of the sky angle and, therefore, less natural light.

In a recent survey of industrial lighting installations, it was found that 25 per cent of the work done was under artificial lighting; and in many individual cases, as high as 80 per cent was under those conditions.

A plant manager, in planning for

operation, must include in his general scheme a means of providing artificial illumination. This necessary expense is only an initial investment, and is a sound investment, if the system is well planned to give proper and adequate illumination. In plants with existing installations, but poorly lighted, it will be found economical to discard the old system and install a modern one. Recommendation as to intensity of illumination depends, of course, on several factors such as the cost of electric energy, the number and the wages of employees, and the value of their output.

Several scientific investigations have recently been made in the study of the speed of discrimination. Dr. Ferree has found that a change of from two to ten foot-candles will practically cut in two the time required to recognize the details of a small test-object; Dr. Luckiesh's experiments have shown that the speed of reading a page of Old English type can be increased fully 25 per cent by the same change in illumination.

In the field of so-called "productive intensity tests," an investigation conducted at the Dover Manufacturing Company's plant showed an increase in production of 12.2 per cent, due to the installation of a modern lighting system, at an increased lighting expenditure of only 2½ per cent of the pay roll. The old system gave an average illumination throughout the room of about 0.7 foot-candles, with an average of 4 foot-candles at the tool-points. The modern system averaged 13 foot-candles.

Another investigation, conducted in the General Electric Company's Schenectady shops, showed that increasing the illumination from 3.8 foot-candles to 11.4 foot-candles, in a section devoted to semi-automatic buffing, increased the production 8.6 per cent. The increased cost of lighting amounted to 0.4 per cent of the increased value of production.

A steel machine shop in Chicago, by increasing the illumination from 3 foot-candles to 11.7 foot-candles, showed an increase in production of 10 per cent with an increase in the lighting cost, of 1.2 per cent of the pay roll.

If an operator, because of the good illumination, saves in more production or in the better quality of the product an equivalent of only three minutes per diem for three hundred days, he will offset the annual cost of the illumination from a 100-watt lamp. Good illumination is, relatively speaking, inexpensive; and its intro-

A machine shop having local lighting.

duction and maintenance are good investments on the part of the factory owner.

### Comparative Low Cost

These estimated figures, illustrating the low cost of good lighting compared with the cost of labor, also illustrate how large may be the losses unconsciously sustained by the factory owner from the use of a poor lighting system. An operator losing, say, thirty minutes a day, loses more than sixty dollars per annum, or about ten times the cost of giving him good illumination.

If a change in the lighting installation has for its purpose a saving in energy consumption, it should be carefully considered. The above comparisons show definitely that a gain in increased output due to good lighting overbalances any possible saving in energy. The lighting installation must meet the requirements of good illumination, even though it involves an increased energy cost.

Of the utmost importance is the question of maintenance. This apparent negligence applies not only to the lighting installation, but to the painting and to the windows and skylights as well. When we consider that there is an absorption loss of approximately 10 per cent of the light, through clear glass, we can, in a measure, realize the loss due to the preponderance of dust- and dirt-covered lamps and reflectors existing in our industrial plants. This is true, also, of the coloring of walls and ceilings the reflection factors of which mean so much from an efficiency standpoint.

Last, but not least, is the question of lamp renewals. The long lamp-life seems to be the policy in

the majority of our installations. The plant engineer fails to differentiate between useful lamp-life and physical lamp-life. The useful life of lamps is approximately one thousand hours. From the initial burning, there is a gradual drop in the illumination until, at the end of this period, the decrease represents, approximately 15 per cent of the initial light, with a decrease, during the same period of but 3 per cent of the current energy. The decrease in illumination after the one thousand hours is of a decidedly greater percentage and the loss in cost efficiency warrants replacement of the lamps.

Cooperation between employer and employee means consideration of each for the other. Physical welfare is of mutual benefit. No one needs to emphasize the absolute necessity of pro-

tecting the eyesight of the worker. If sufficient illumination is not provided, the eyes are continually subject to strain in their attempt to discern detail. This rapidly fatigues, lowers the bodily efficiency, and may produce permanent injury. On the contrary, with plenty of light, if brilliant sources are permitted to be in the range of vision, bad conditions exist. We oftentimes hear the statement that a room is over-lighted. With the low intensity prevailing generally, in comparison with outdoor illumination, this statement is without foundation. It is only because the layman considers the glare, instead of the illumination effect.

### Glare Can Be Eliminated

A concrete example, of which there are many, comes to the writer's mind from a complaint of one of our Philadelphia weaving mills. The installation consisted of three drop cords, with bare 50-watt lamps over each loom. The lamps were directly in the range of vision of the workers, and were the cause of headaches, of which the management received many complaints from the large force of women employees. The installation was corrected, so that two ceiling outlets, equipped with R. L. M. reflectors and 100-watt bowl enameled lamps, were installed between each two looms; and the drop-cords were equipped with steel-dome reflectors. The local lighting was necessary in order to prevent shadows from the rapidly-moving shuttles. The results conserved the eyesight, increased the lighting intensity, and improved the output.

Same shop with general lighting installation made.

Subjecting employees to continuous work under insufficient illumination eventually means failing eyesight, thus incapacitating experienced workmen at the very time when they should be yielding the biggest return on the investment made in their training.

The question of shop sanitation is one that is receiving increasing attention for an employer fully realizes that a healthy operator is an asset to his plant. Proper illumination is one of the greatest helps in attaining this result. A dark corner, for instance, tends to gather dirt because of its be-

ing less observed by the factory management.

Dark-colored or dirty walls are not only depressing but cause a loss by absorption of the light falling on them. The reflection factor of white walls is about 80 per cent, whereas only about 48 per cent of the light striking it is reflected from a light-green wall, and only 15 per cent from a dark-gray wall.

Psychology plays an important part in mill management. A well-lighted, well-ventilated and clean factory promotes a more cheerful feeling, and tends to prevent a discontent which,

in many cases, causes labor trouble. It is obvious, therefore that a well-lighted plant increases production, reduces spoilage, conserves vision, reduces accident loss, and aids sanitation, thereby promoting health,

Obviously, these conditions, in turn, promote contentment and loyalty, thereby reducing labor turnover. Carnegie once said, "You can take away my factories and my plants; take away my railroads, my ships and my transportation; take away my money; strip me of all these, but leave me my men; and in two or three years, at the most, I will have them all back again."

## The Heart Disease Problem in Industry\*

### Ordinary Heart Infections Rather than Special Occupation Cause Symptoms

BY PAUL D. WHITE, M.D., BOSTON, MASS.

THE relationship of the individual with cardiac symptoms or signs to industry is a question much debated and of growing concern. Experiences in the cardiac clinic of the Massachusetts General Hospital, in the cardiac problems of the soldiers of the great war and after, and in a private practice in heart disease have presented to my mind certain conclusions that I believe are worth reporting.

First of all, there is no such complete entity as industrial heart disease. Cardiac symptoms and signs in the industrial worker are the result almost invariably of nervous fatigue or effort syndrome, or of damage by rheumatic fever, syphilis, arteriosclerosis, high blood pressure, or hyperthyroidism. Sometimes two causes are responsible in the same individual. It is likely that in some cases the wear and tear of work may be responsible in part for hypertension or arteriosclerosis, but even more may the wear and tear of late hours, overeating, family worries, and alcohol play their part. Rarely lead poisoning helps in the progress of arteriosclerotic heart disease, but this is only a drop in the bucket.

Symptoms of serious heart trouble may first appear during work, and often some unusual strain or fall or blow is held responsible for the whole trouble when as a matter of fact the stage was all set by progressive in-

*There is no such complete entity as industrial heart disease. Cardiac symptoms and signs in the industrial worker are the result almost invariably of nervous fatigue or effort syndrome, or of damage by rheumatic fever, syphilis, arteriosclerosis, high blood pressure, or hyperthyroidism and rarely result from accidents such as wounds to the heart, a blow on the chest, or unusual physical strain.*

*Industry has to deal with both the true heart disease type and the functional disorder type. Thousands of the latter have been classified as cardiac cripples and denied work. It is for industry, with proper protection to itself of course, to find a place not too exciting for these.*

sidious change in the heart and merely awaited the proverbial last straw. This fact is notably applicable to industrial workers after they have passed fifty years of age, but not infrequently the rapid deterioration of a syphilitic heart in the early forties will cause incapacitation and death in middle age. One of the most vital defences against these bolts from the blue for the employer in such cases is regular periodic physical examination of the employees. There is, of course, no question that

in many of these cases the industry is the exciting factor for the first appearance of symptoms, but also almost invariably industry is not responsible for the fundamental heart disease. At times the aggravation may be extreme, as in the unusual but unquestionable reported cases of valve, heart wall, or aneurysmal rupture under strain. So far as pathological examinations in these cases are concerned, however, the valves, the aorta, or the heart muscle are generally found diseased, and with careful physical examination this disease might have been discovered before the accident and the individual properly treated and given lighter work.

Accidents may involve the heart in three ways. In the first place, there may be the immediate reflex cardiac disturbances from injury to other parts of the body. Palpitation and tachycardia are of course frequent accompaniments of accident, so frequent in fact that we do not misinterpret them as evidence of actual cardiac injury. The second way in which the heart may be involved is, however, often very misleading and puzzling. Following accidents particularly severe ones in nervous people or where there is a good deal at stake, effort syndrome is very common and may be mistaken for actual heart disease. Palpitation, dyspnea, and even precordial pain may be present without any actual heart damage. Some of the cardiac irritability may be shown as premature beats or par-

\*Read before the American Association of Industrial Physicians and Surgeons, St. Louis, May 23, 1922.

oxysmal tachycardia. However, other evidences of a nervous high-strung temperament are always present to give the necessary clues,—restlessness, evidence of worry, tremor, sweating and tachycardia on physical examination, exaggerated knee-jerks and so on. Effort syndrome of this type is, of course, commonest in young people who have inherited a nervous temperament, but it may occur in middle age also if there is enough provocation.

In old people, although it is still possible to find nervous irritability, the possibility or probability of arteriosclerosis should make us more wary in diagnosing effort syndrome alone. When the two are combined—arteriosclerosis and nervousness—the task of discrimination of the percentage of symptoms due to the one and to the other may indeed be difficult. However, it may safely be said that the vast majority of cardiac symptoms following accidents are due to extra-cardiac causes acting reflexly through cardiac nerves.

That actual injury to the heart may come from accident is well recognized. There are three ways in which this injury may be produced. First, there are the rare penetrating wounds of the heart and great vessels about which there can rarely be any difficulty in recognition. Then come the even rarer cases of crushing injuries to the chest or blows or falls resulting in rupture of ventricular or auricular wall, of aorta, or of valve cusps. Finally, there are the cases of uncertain frequency but also doubtless very rare in which sudden violent effort causes heart damage—rupture of valves, of ventricle, or of aortic aneurysm.

#### Barié's Valve Rupture Reports

An interesting account of a series of 38 cases of ruptured valves of the heart was published in 1881 by Barié. He collected 31 cases from the literature and added 7 more cases previously not reported. There were 19 cases of rupture of the aortic valve cusps, 16 of rupture of the chordae tendineae or columnae carnae supporting the mitral valve, and 3 of rupture of attachments of the tricuspid valve. He reported no cases of pulmonary valve rupture and I have found but one in the literature. Of the 19 aortic valve ruptures, 10 were what Barié called spontaneous,—that is, not the result of external trauma. Lifting of great weights, pushing a heavy load, running very hard, climbing a mast in a storm

were the type of effort resulting in the aortic valve rupture. Falls on hard surfaces and heavy blows or kicks on the chest were the type of external trauma resulting in the same phenomenon. Both can be accounted for by the sudden increase in pressure on the aortic valve with the aorta full of blood, that is, in early diastole. Barié produced aortic cusp rupture experimentally in hearts freshly removed from bodies immediately postmortem. He found that water pressure varying from 116 mm. to 484 mm. of mercury ruptured the cusps in several cases. Actual figures were 116, 184, 278, 292, and 484 mm. On one occasion he distended the aorta *in situ* and then struck the thoracic wall with a hammer. On examining the heart he found a tear in the aortic cusps. Of 11 cases autopsied, mention of the number of cusps torn is made in 9. In 6 of the 9 two cusps were injured and in 3 but one cusp. The septal cusp was most often damaged. No women were found with rupture of the aortic valve.

In Barié's series, spontaneous rupture was more common than external trauma rupture in the ratio of 5 to 2. In only one case experimentally was he able to break the mitral attachments and for that he had to exert an intra-ventricular pressure of 1,050 mm. of mercury; in the same heart he broke an aortic cusp with 184 mm. mercury pressure. He found almost invariably that the ventricular wall broke before he could rupture either the tricuspid or the mitral valve. There was never sudden death in Barié's cases but the prognosis was almost invariably grave, death resulting with heart failure (and marked cardiac hypertrophy) after a few weeks, months, or years.

In 1910 Ranelletti compiled the cases of valve rupture from the literature. He found 49 cases of rupture of the aortic valve, 27 of the mitral, two of the tricuspid and one of the pulmonary.

The question of especial interest is as to whether or not healthy valves will tear. There are enough autopsies reported to show that such is possible, in fact a large number of the aortic valve ruptures seemed to be in fairly normal hearts. Without doubt, aortic sclerosis and syphilis predispose to rupture and less pressure would be needed in such cases to break the cusps than in normal cases. Rheumatic involvement also may be a factor. The mitral valve cases have nearly always shown evidence

of disease—endocarditis, sometimes malignant, which had weakened the chordae and columnae. Occasionally holes and tears in the auriculo-ventricular valves have been found in hearts as the result of ulceration without any exciting factor such as sudden effort or external trauma. At times, on the other hand, the endocarditis seems to have followed the trauma.

#### Rupture of Auricular Walls

Rupture of auricular and ventricular walls and aorta are much more common than rupture of the valves and were recognized much earlier. It is said that Harvey reported the first case, a rupture of the left ventricle, while it was about one hundred and fifty years later that Senac in 1778 reported the first case of rupture of valve cusps. Heart and aortic ruptures have been reported frequently. The same statement, I believe, may be made concerning them as concerning valve ruptures. Although the healthy ventricle, auricle, or aorta may be torn if sufficient pressure, almost invariably the result of external trauma, is exerted on it when distended with blood, it is quite certain that such rupture is far more apt to occur if the heart wall or aorta is diseased as in cardiosclerosis or aortic aneurysm. Spontaneous rupture without sudden effort means disease. Examples of healthy men traumatized to the extent of rupture of heart or aorta are as follows: (1) A young man of 23 years of age fell 45 feet and died almost instantly. At autopsy a tear 25 centimeters long was found in his left auricular wall with his pericardium full of blood. Also there was a rupture of the right lobe of the liver. (Howat, *Lancet*, June 2, 1920.) (2) A healthy laborer of 40 years of age was struck by a large mass of falling earth a glancing blow on the back, and killed instantly. At autopsy his left pleural cavity contained 38 ounces of blood. Opening into it were the gaping ends of the descending aorta cut as if with a knife at right angles. The break was 3½ inches from the aortic valve. The aorta was healthy. (Copeland, *Jour. A.M.A.*, November, 1914.)

The last point to consider with reference to the effect of accident on the heart and aorta is as to whether partial injury can be caused to the wall of either without actual rupture; i.e., can there be a tear or weakening which may result in aneurysm of a healthy heart or aorta.

Of this we have no certain proof. It is a possibility, but in view of lack of proof we should consider it a very remote possibility. If the heart or aorta is diseased to begin with, there is far more chance of such an occurrence.

### Cardiac Cripple in Industry

In answering the question as to whether cardiac cripples are of use in industry, accurate diagnosis is in the first place all-important. A good many workers are limited in their strength or endurance by cardiac symptoms but a large percentage of these have not heart disease.

The appalling frequency of the irritable or nervous heart or effort syndrome, as the condition has also been called, in the armies of the great war is to some extent duplicated in civil life. Over one-fourth, actually 28 per cent of a group of 450 patients with cardiac symptoms or signs that I have seen in consultation have had only functional disorders so far as the heart is concerned,—effort syndrome, extrasystoles, or functional murmurs,—and have revealed no real heart disease. This is even more true of industrial workers and of the veterans of the world war still sheltered under the wing of the government. Of 53 soldiers with heart symptoms or signs labeled as heart disease, whom I have examined recently at the Public Health Service Hospital on Parker Hill in Boston, 30 or 57 per cent showed no evidence of heart disease.\* They had all tried to work, some of them conscientiously and some of them not conscientiously. Their symptoms had made them seek relief. There is little question that they nearly all have real symptoms, and disagreeable ones too, but the important points are these,—their symptoms are not symptoms of organic heart disease and these men are better off at work than idle. Idleness is at least as harmful as over-exertion. There is a happy mean; there is work somewhere suited for these men, and they should be urged to find it and not be invalidated and labelled for life as cardiac cripples. They have long, and should have, useful lives ahead of them. Merely because someone has elicited a story of dyspnea on exertion or excitement or a systolic whiff or an extrasystole at the apex in one of these chaps, he should not be stigmatized as a cardiac. I do not mean that these men are deceitful, most of them are

not;—their symptoms are real. But many persons have irritable hearts and might easily stop work if they paid attention to every premature heart beat or faint sensation. Some of these men will do well at some leisurely occupation in the open air; others will do just as well indoors.

It is necessary to classify the individuals with real heart disease according to the cause of their heart disease and according to their functional capacity, as well as in the incomplete old-fashioned method of stating the structural defects present. Thus, given cardiac hypertrophy, or aortic regurgitation, or auricular fibrillation, it is of great value in judging the future outlook as well as the present capacity to know whether rheumatic fever, syphilis, arteriosclerosis or other factor is chiefly responsible. Take for example two men of 40 years of age with aortic regurgitation and with few symptoms. Is the cause rheumatic infection or syphilis? If the latter, the future is apt to be dark, death often supervening within a few years, while in the former case there may be many years of useful work ahead. Of course, it is also important to treat these cases properly, with antiluetic measures if syphilis is the cause.

Etiologically we should try to diagnose a given case as congenital, rheumatic, syphilitic, hypertensive, thyroid, arteriosclerotic, and so on. Structurally we can state the presence or absence of cardiac enlargement, valve lesions, aortic dilatation, or pericarditis. And functionally we should state the kind of arrhythmia or other disorder of the heart beat which may be present, and whether or not there is evident heart failure. There are two important types of failure,—that in which the presenting evidence consists of dyspnea and edema, the so-called congestive failure, and that in which pain is paramount, the so-called anginal failure. Care should be taken not to call heart pain acute indigestion simply because there is some gas in the stomach or bowels.

Finally, there are all gradations of failure and functional capacity of the heart. These are best expressed as follows: (1) No failure—ability to carry on customary activities without dyspnea or pain; (2) Slight failure—partial restriction of ability to carry on customary activities without symptoms; (3) Moderate failure—considerable restriction of this ability; (4) Marked failure—inability to carry on any customary activities

without dyspnea or pain; (5) Extreme failure—symptoms and signs persisting even with the individual at rest in bed.

### Functional Tests

Simple questions will suffice to determine roughly in the scale represented above where an individual fits, but for more definite decisions as to ability to undertake certain work some tests are necessary. All the tests we have are rough guides only. They are in the main but clues to the physical fitness of the individual. Since physical fitness includes cardiovascular efficiency, to that extent only may such tests be called cardiovascular functional tests. Dr. Brittingham, working in my clinic this past year, tried out the two most suitable tests of respiratory and exercise type, vital capacity measurement and dumb-bell lifting. The vital capacity test consists of the record of total amount of air in cubic centimeters which can be expired into a spirometer after a full inspiration—the best of three trials being taken. This is a quantitative measure of dyspnea and may be normal in heart failure of the anginal type. It has wide ranges of normal, body surface being used as the measure for standardization. General physical fitness is another factor as well as body surface to cause normal variations. For example, the average charity class of the community gives a lower average normal than those who have lived under better conditions of life. Well marked reductions of vital capacity, below 70 per cent of the estimated normal, almost always mean disease in heart or lungs, and we must remember that lung pathology may give us low readings as well as cardiac disease. Exceptionally, individuals, large or small, may give very low readings, even with perfectly normal hearts and lungs. Psychoneurosis, such as occurred in shell shocked soldiers, is in these the cause. Also we must remember that individuals with well marked heart disease without heart failure may have perfectly normal vital capacities. Thus this test is of limited value, and reductions below the normal standard must be interpreted with care so far as the heart is concerned.

The best example of the exercise tests which Brittingham tried was the test of the blood pressure reaction following dumb-bell lifting. The use of small dumb-bells proved futile because often the skeletal musculature would become exhausted before any distinct cardiovascular reaction could

\*In another group of 100 unselected, so-called "cardiacs" in this same hospital, Dr. McCrudden found 64 without heart disease.

be secured. Of course, in patients with obvious heart failure one might use small dumb-bells, but for these the exercise test is unnecessary. Swinging two twenty-pound dumb-bells from arms-length overhead down between the legs and back at the rate of twenty times a minute in the course of one-half to one or two minutes so acts on the cardiovascular system that a delay in rise of systolic blood pressure beyond the normal of one minute is finally produced with also a delayed fall back to the normal pre-exercise level. This has proved a rough guide to physical fitness but little more, for examples such as the following may be multiplied. One day two men were tested; one with rheumatic heart disease and aortic regurgitation went easily through the test for a minute without any delayed rise of blood pressure; the other with normal heart and effort syndrome was unable to finish the minute's exercise and had a distinctly delayed rise. As a test of general physical fitness such an exercise is of value and may be simple observation of the way the individual performs will do about as well as the laborious blood pressure estimations and a bar will do as well as dumb-bells.

After determining by simple observation and questioning, and by the use of some simple exercise test what a man's functional physical capacity may be, the final answer to what he is capable of doing must come from testing him at the work itself. Short physical efficiency tests are all and always open to the following three objections: first, the test is short and the work long; second, the test is carried out under much more excitement, probably, than the work; and third, the test and the job may utilize altogether different muscles.

In conclusion there are thousands of individuals with irritable hearts or with real heart disease who are fit for work and who will be benefitted by work. How can we get them to the work? In the first place we must convince them that they can do something, that they have after all a place in the community. Second and perhaps more difficult, we must persuade industrial employers to take on these people with irritable hearts and true heart disease. From the individual with simply an irritable heart there is little to fear—nothing in fact from the cardiac standpoint, but sometimes nervous prostration. In the case of the true cardiac, however, there is often trouble ahead. With perfect reason employers must not be held re-

sponsible for the onset of symptoms of failure in these individuals whom they have been kind enough to take into their employ. They must be protected, especially in the case of the man with syphilitic heart disease. It seems to me that there would be no difficulty through the country at large to get suitable occupations for people with heart disease if absolute assurance could be given their employers in accepting them that the onset of crippling symptoms or signs referable to their circulatory system could not be laid at the door of the industry. This is a reasonable solution of the difficulty now before us. By this scheme a person with an irritable heart or with heart disease may work wherever he is qualified mentally or physically—it does not matter at what job.

Finally, all this discussion about the heart in industry, important as it seems, may some day, centuries from now, seem ancient indeed, when the prevention of heart disease in youth by the extensive wiping out of rheumatic infections, syphilis, hyperthyroidism, and early hypertension is an accomplished fact. By the time arteriosclerosis sets in to limit cardiac capacity in that far-distant future, the life of work will have been duly completed. Therefore, while we are busy trying to decide what to do now with our cardiac cripples, let us also be building the foundation of that far more important work, the prevention of heart disease.

### Industrial Hygiene Section of Public Health Association

Joint sessions of the Industrial Hygiene Section of the American Public Health Association and the Ohio Association of Industrial Physicians and Surgeons will be held during the fifty-first annual meeting of the American Public Health Association scheduled to take place in Cleveland, O., October 16 to 19, 1922. Dr. Wade Wright, as chairman of the Industrial Section of the Association, and Dr. Sydney S. McCurdy, president of the Ohio Association, will preside at the meetings. The special program follows:

TUESDAY, OCTOBER 17, 9:30 A. M.

- (1). Business meeting, Industrial Hygiene Section, American Public Health Association.
- (2). The Tuberculosis Problem in Industry—(Stereopticon Illustration). Horace John Howk, M.D., assistant medical director, Metropolitan Life Insurance Company. Physician in charge Metropolitan Life Insurance Sanatorium, Mt. McGregor, N. Y. Discussion led by H. A. Pattison, M.D., supervisor, medical service, National Tuberculosis Association, New York City, followed by James A. Brit-

ton, M.D., International Harvester Company, Chicago.

(3). Industrial Dermatoses—(Stereopticon Illustration). Harold N. Cole, M.D., associate professor Dermatology, Western Reserve University, Cleveland. Discussion by Charles Baskin, Akron, O.

(4). Health Education in Industry—(Stereopticon and Motion Picture Illustration). Ralph W. Elliott, M.D., manager, Medical Department, National Lamp Works of General Electric Company, Cleveland.

WEDNESDAY, OCTOBER 18, 9:30 A. M.

(1). Business meeting, Ohio Association of Industrial Physicians.

(2). President's address. Sydney S. McCurdy, M.D.

(3). Causes of Absenteeism Among Store Workers. Charles A. Swan, M.D., medical director, Halle Brothers Company, Cleveland. Discussion led by A. B. Emmons II, M.D., executive secretary, Harvard Mercantile Health Work, Boston.

(4). Computation of Partial Loss of Vision and Hearing. William Mehl, M.D., Buffalo, N. Y.

(5). Mental Hygiene in Industry. Frederick W. Dershimer, M.D., National Lamp Works, Cleveland. Discussion led by A. G. Cranch, M.D., medical director, National Carbon Company, Cleveland.

(6). Heat Hazards in Industry. G. H. McKinstry, M.D., medical director, Spang, Chalfant & Co., Pittsburgh.

Headquarters are at Hotel Statler.

### Industrial Home Work for Children

The study of industrial home work of children, U. S. Children's Bureau Publication No. 100, was made in Providence, Pawtucket, and Central Falls, R. I., in 1918, at a time when none of the labor laws of the state applied to work done in the home. It was found that at least 5,000 children under 16 years of age had done home work in the course of a year, and that over 7 per cent of all the children 5 to 15 years of age, inclusive, in the three cities had been engaged in such work during that period. Of the 2,338 children who had worked at least one month out of the year and had received compensation, 4 per cent were under 6 years of age and 46 per cent were under the age of 11. Injuries, especially accidents from machines installed in the homes, in addition to eye strain and fatigue reacting upon school work, were frequent. A possible danger to the health of the community was found in the fact that large numbers of families reported doing home work while members of the family were ill with infectious diseases. In some cases the sick persons took part in the work. The testimony of manufacturers using the home work system indicates, the report states, that industrial home work in this district could be abolished with few business losses. Shortage of labor was the chief reason given by manufacturers for the employment of child labor in the home. Others explained that home work saved in overhead costs, while some made the claim that they were actuated in its use chiefly by motives of charity.

# Problem of the Mental Misfit in Industry\*

## Mental Hygiene Will Help to Solve Many Maladjustments in Industry

BY GEORGE K. PRATT, M.D., MEDICAL DIRECTOR, MASSACHUSETTS SOCIETY FOR MENTAL HYGIENE, BOSTON, MASS.

THE student of industrial conditions is quickly impressed by the fact that the problem of the mental misfit in industry, like that of the army, finds a common source in the community in general. The worker, that all inclusive term, is also the soldier, the scholar, and the citizen. That he may at times be maladjusted in the factory is as certain to be as that he is occasionally out of tune in a military environment or in that of the university.

While today, courts, schools and army have all to some extent, at least, readjusted their mechanism to allow for recognition of the individual and his character differences, industry has lagged behind. With a few notable exceptions, modern industry appears still to think of its shop personnel in terms of so many "hands," rather than so many "hands" plus an equal number of minds and nerves and instincts and emotions. In the past decade, tools, materials, shop practice, and machines have been standardized to a high degree. Automatic machinery more and more supplants human effort in an attempt to reduce even minute variations in the appearance and quality of the finished product. The modern industrial concern has succeeded in bending to its indomitable demand for uniformity every item concerned in production but one, the worker. He alone resists fusion in the smelter of homogeneity; and if, during the process, his rebellion should boil over then industry has participated in the production of another misfit.

As one may reasonably assume that the type of worker manning industry is essentially the same as that which comprises the bulk of the community, it is equally reasonable to expect that he will possess a similar susceptibility to those factors which make for mental impairment, allowing for the differences of industrial coloring to his symptoms. The community is dotted here and there with feeble-mindedness; so is industry. The community is handicapped by its constitutional inferiors and neurotics; so is

industry. The community has its rebels against the civil and social codes in its psychopaths and its irreconcilables, while industry finds it necessary to contend with its radicals and agitators.

Just as some communities today deny the existence of a mental health problem within their borders, so do some industrial concerns reject the suggestion that a goodly portion of intramural friction, excess spoilage, high labor turnover, excessive accident frequency, and a dozen and one other shop problems whose ultimate expression is to be found in increased production, lowered dividends, and augmented plant cost and insurance, may all have a common source in mentally insanitary conditions within their own confines. The manager of a large paper mill derided the suggestion that a falling off in production and a seething unrest among the operatives of a certain roll mill might have its origin in the instability of temper and fluctuation of purpose of a newly appointed foreman, who was obviously on the edge of a maniac-depressive upset.

### Accident Repeaters

An automobile factory installed at great expense an elaborate system of automatic safeguards for their machines. Ten months later they were deeply concerned to find that their accident frequently had declined only about one half of what they had been led to hope. Analysis of the figures, however, showed that while the total number of accidents remained unduly high, they were occurring to a smaller group of employees. In other words, under safeguard conditions, most of the accidents were occurring to a relatively small group of "repeaters" who were being injured again and again. Several of this group were later found to be definitely feeble-minded; and a few more to be emotionally unstable and negligent to an unemployable degree. This incident suggests a parallel between the two mental mechanisms of the industrial accident repeater and the court recidivist.

Feeble-mindedness in industry is

not, however, the wholly unmitigated menace it often appears to be. To be sure, an unrecognized defective may create much misunderstanding and trouble; and the fact that the higher grades especially give little physical hint of their limited intelligence makes their employment easy and subsequent detection difficult. Yet properly assigned and in certain jobs the defective is a satisfactory and even valuable worker. Indeed, in those industries where automatic machinery largely predominates, such as in automobile and, to some extent, in textile plants, the subnormal individual is often deliberately sought out. Average manual skill and even less than average intelligence are the easy demands that the automatic machine makes of its operator. Mental effort of a minimum amount is required, and the unimaginative, content-with-the-present mind of the defective plods along at his task quite unaware of the deadly monotony that quickly creates aggravated "labor strain" in his more highly endowed brother.

For such jobs the subnormal workman is an almost ideal type. He obeys without questioning, he is content to be led, he indulges in no dangerous "thinking" about his fancied socio-industrial place in the world, and, being essentially a creature of fixed habit, he soon learns the simple operation of his automatic machine, and cannot easily be induced to depart from the routine thereof. As witness to the veracity of these assertions, one has only to recall the testimony of divers employment managers, no small percentage of whom also assert that the highly automatized factory actually tends to place a premium on limited intelligence.

Most of the objections to the defective in industry appear to arise only when he is maladjusted. A man of twenty-six with a mental age of ten and a slow reaction time will almost certainly in the course of time sustain an injury if operating, say, a high-speed grinder, or perhaps a drill press where a measure of fine judgment is demanded.

An individual of this type, after

\*Read before the Fifteenth Conference of Pennsylvania Industrial Physicians and Surgeons at Harrisburg, Pa., May 25, 1922.

accurate psychometric tests, was discharged from the army as a "mental defective." He was employed on the recommendation of a Federal Vocational Training Board by an automobile firm as a helper on their loading dock. Admirably fitted for this work, being strong and willing, he soon sank into a comfortable niche, and gave eminent satisfaction. Indeed, so well did he and his job fit each other that, when an opportunity arose, a well-meaning and patriotically inclined foreman promoted him on his statement that he could operate an automobile to a position as truck driver. The short hauls in the plant between assembly department and freight platform were easily negotiated, and for a time all went well. Then one day during the absence of an older driver he was sent across the city to pick up a five ton load of motors and told to "hurry." The return trip necessitated crossing a railroad track, and the inevitable happened. A combination of slow reaction time and chronically defective judgment brought the loaded truck and a fast freight together on the track at the same moment, and, in addition to several thousand dollars' worth of damage to truck and motors, the family of the dead boy brought heavy suit. Properly fitted to a job compatible with his stunted intellect and abilities, a mental defective above the grade of imbecile seldom causes trouble. Misplaced, he is a never-ending menace to himself and all about him.

### Problems of Psychoneurotic

Just as in the community we find friction, misunderstanding, and distress ever following in the wake of the psychoneurotic, so do we find similar symptoms in industry. The same mechanisms that seek to translate the mental difficulties and conflicts of the citizen into terms of physical discomfort and ill health operate in like fashion in the workroom. Neurasthenia, that type of mental disorder re-enforcing or simulating physical invalidism, takes as much toll in the shop as in the home; and its industrial severity is further enhanced by the fact that the foreman recognizes it for what it really is as infrequently as does the physician.

Poorly balanced emotional equipments do not stand out in bold relief as do crippled joints or a wooden leg; and when their owners become ineffective or give vent to easily aroused anger or seem constantly irritable, custom is prone to attribute such out-

bursts to "cussedness" rather than to a little understood "sickness."

Thus, the neurotic bank clerk, complaining of constant headaches, of early fatigue, of constipation and irritability, may be subconsciously struggling against dislike for a frivolous wife hastily married in a moment of sex madness. He is the emotional, if not the blood brother of the workman whose back habitually aches, whose anger blazes forth on trivial pretexts, who is over-sensitive and over-tired, whose work is often spoiled, and who, underneath all this, may be blindly revolting against a shop life whose only hold is the increased financial gain for his family that a coveted farm existence cannot offer. It matters little what the precise process may be, the outward results are similar; and, as the struggle lapses into chronicity, both bank clerk and workman are likely to become known as "grouches" or "touchy," and the rest of the crowd begins to edge away. The end results are invariably seen, but seldom the cause.

Industry teems with this unrecognized type. Production and accuracy of work are maintained at fearful expense to the neurotic's ability to repress, and often inefficiency crops out despite frantic struggling. Fatigue of mind brings about inattention and lack of concentration, just as fatigue of mood is marked by a mild depression, a tendency to worry and an unenthusiasm or even dislike for those persons or things formerly held in high esteem. The creation of imaginary, selfmade situations is a peculiarity of this type; and more than one serious injury has been sustained during a moment when the attention was distracted from the work in hand to the distorted fields of day dreaming in which the neurotic seeks comfort by artificial surcease from conflict.

More spectacular, certainly more vexatious and more difficult of detection, is the industrial psychopath and inferior. While psychiatry has long been more or less familiar with the unreliability, the penchant for precipitating trouble, and the habitual dissatisfaction of this type, industry only recently has come to connect his maliciousness and anti-social conduct with certain of its labor agitators and chronic "kickers." The neighborhood "grouch," perpetually suspicious, litigious minded, and socially disgruntled, has his counterpart in the grudge-bearing workman, querulous, resentful of authority, and

always "in bad" with his fellows. This man is frequently of more than average intelligence and is often a skilled workman as well. But tenure of position is constantly being threatened by one sort of dissatisfaction or another. This job is too hard for the wages paid; that one is dominated by a disliked foreman; another is with a firm whose welfare personnel is thought too zealous; and so on, *ad infinitum*.

### Other Industrial Misfits

In a paper on this subject by Southard, a short time prior to his death, Jau Don Ball is quoted as offering a list of industrial types who might well come under the designation discussed. Among these he names "queer guys, eccentrics, disturbers, querulous persons, unreliable and unstable fellows, misfits, the irritable, the conscientious, litigious, bear-a-grudge, peculiar, glad hand, gossipy, roving, restless, malicious, lying, swindling, sex pervert, false accuser, abnormal suggestibility, and mental twist types." While fully agreeing with Ball that "it could not be concluded from this or any other examination that all strikers, whether agitators or not, are psychopaths," one cannot escape the conviction that in the pathologic dissatisfactions, the anti-social activities, and the oftentimes brilliant but distorted cerebrations of these individuals, the seeds of more than one case of shop unrest and labor difficulty are to be found. Stewart Paton calls such manifestations "the defense reactions of 'inadequates,'" while Pound believes such types have a lowered threshold of resistance to "labor strain." Classify them as you will, the fact remains inescapable that the industrial psychopath is a thorn in the side of every plant management. No shop is too small to harbor at least one of them, and one who may be especially maladjusted can destroy in a week the entire morale of a plant which required years of patient effort to build.

It is felt desirable to make brief mention of two other types of mental misfits in industry. One consists of a group of employees who develop certain mental disorders on the job. Most common of these conditions is developing general paresis, a premature arteriosclerotic process, or an incipient dementia precox. While causative factors differ in each, they all have a common initial symptomatology in "change of character." Be ware of the old and trusted workman

whose shopmates confess to puzzlement because he seems "different." Perhaps, from a quiet, sober, self-respecting demeanor, he commences to grow careless, boisterous, obscene of speech, and forgetful. These are but a fraction of the character changes that are the outward, warning expression of a deteriorating organic mental process. It is not only the aged worker suffering from a frankly recognized senility that undergoes these disorders. Only too often they afflict the middle-aged man from forty to fifty. General paresis is no respecter of persons. Premature arteriosclerosis may appear long before normal senescence is expected; and dementia precox is, of course, a spectre of youth.

The second type of industrial misfit is equally important. In fact, strictly speaking, he has no title whatsoever to the designation "mental" misfit for he is as normal minded as one could wish for. And yet, he often creates a problem. Reference is made to the superior type of workman, superior in ability and intellect, who, nevertheless, is placed in an inferior job and is not promoted. Nothing can be quite so soul-deadening as the situation of the employee with his family, working at a task that consumes only a minor portion of his skill and ability, and who, for a hundred and one economic reasons, may not find a more advantageous location possible. Friction and dissatisfaction as inevitably follow in the wake of this man as they do in that of the inferior worker in the high grade job. Such a situation rapidly tends to destroy the morale of the superior workman; and as surely as the sun rises, he is sooner or later going to express his dissatisfaction in terms of unrest and resentment. Thus is one kind of agitator born, and an especially menacing one, for, being anything but a psychopath or a defective, he diverts his superior intelligence from a job that can use only part of it to stirring up his fellows with the surplus. On the other hand, like all the other types discussed, fit this fellow to a task 'n keeping with his ability, promote him when he deserves it, and his mischief-making tendencies dissolve into thin air.

These three types, the mental defective, the psychoneurotic, and the psychopath contribute a major share to the problem of the mental misfit in industry. The solution of each is in some ways, an individual matter. Practically speaking, however, the

effects of each overlap and cannot be separately untangled.

While attempting no dogmatic solution of these problems, one is disposed to hope that their broader aspects may be lightened by an extension of the mental hygiene movement which has already invaded the community, the courts, the schools, and the army. Mental hygiene has assisted in the untangling of many a knotty social and legal problem by explaining the reason for certain conduct or behavior manifestations. In a very practical way it has been of inestimable value to society in demonstrating, for instance, that many a so-called criminal is a mental misfit in the social code, and again, that certain children, who may habitually lie or steal or run away, may need not punishment but to be understood in order to restore them to a plane of future usefulness.

#### Mental Hygiene Policy

Mental hygiene opposes the old viewpoint of medicine and the law that dealt only with end results and substitutes therefor a policy of prevention of mental disorder, a scientific possibility whose practical success psychiatry has amply demonstrated.

The roots of the problem lie deep in the instinctive life of man—be he soldier, citizen, or workman. That the industrial workman is recruited from the community, and that, ergo, the problems of these two bodies, in the final analysis, should be similar, is so obvious as to scarcely warrant comment. And yet, until industry as a whole studies the individual and his problems, the mental misfit will continue.

#### DISCUSSION

DR. A. M. COLCORD, plant surgeon, Carnegie Steel Company, Clairton, Pa.: The industrial surgeon must be a psychologist; he must constantly study the mental side of the problems of malingering, strikes, inefficiency, and accidents. A large proportion of the latter are the result of something wrong on the response side or the mental side. The Industrial physician must study how the individual will stand stress such as excessive worry, excessive heat, etc. He must study cases of maladjustment and attempt to eradicate early symptoms of mental impairment. By so doing, the industrial physician will work a benefit not only to his own particular plant but to the person himself.

DR. J. E. AMBLER, Pittsburgh Plate

Glass Company, Ford City, Pa.: I have found that an enforced rest of from one to three days following even a trifling injury has beneficial results. This gives the nervous system which has been impaired by the shock a chance to rest and prevents serious accidents which often follow slight injuries.

#### Pictures Utilized in Department Records

One of the more recent acquisitions of the Department of Labor and Industry in Pennsylvania under the administration of Commissioner Connelley has been a Division of Illustration. For some time it has been felt not only by the commissioner but by the heads of bureaus that a better understanding of their work might be advanced by photographs, photostat copies of charts, and illustrations which would have an educational value.

The Industrial Board has been the latest branch of the department to embrace the services of this division when it adopted a ruling requiring the illustration of safety standards. The recent report of the Employment Bureau made excellent use of this service by showing the various state employment offices in half tone illustrations.

The Bureau of Rehabilitation has a remarkable collection of pictures of cases obtained by the department photographer, for special purposes, either for the education of people or for the enlightenment of departmental personnel when photographs are in order. The supervision of the educational display is left entirely with the Division of Illustration.

"Children of Wage-Earning Mothers—A Study of a Selected Group in Chicago." U. S. Children's Bureau Publication No. 102, covers 843 families of working mothers in which there were 2,066 children under the age of 14 years. It was found that gainful employment of mothers of young children frequently means inadequate care of the children, or no care at all during the day, retarded progress in school, and over fatigue or ill-health of the mother. Measures for reducing the necessity for wage earning by mothers of young children, the report states, includes improved economic conditions that will make the father's earnings more adequate; training of mothers in household management and the care of children; preserving the normal family group.

# Physical Rehabilitation in Industry

BY OSCAR M. SULLIVAN, DIRECTOR OF REEDUCATION, MINNEAPOLIS, MINN.

THE rehabilitation of a disabled person is an activity that has many phases. This is made manifest by the diverse state systems that were created before the Federal act was passed and began exerting its influence in the direction of standardization. Some of the state systems tended to emphasize the physical side, others the educational side and still others the social welfare side. It is possible to maintain a good theoretical argument that any one of these phases should be the dominant one. However, at the present time the advantage from the pragmatic standpoint is with the system that gives first place to the educational side, for the reason that the Federal law is an educational one and necessarily leads to the development of this field.

But even with the educators in charge of the work, it is not likely that the importance of physical rehabilitation will be or can be slighted. It is obvious that if a disabled person can by proper medical and hospital treatment be physically rehabilitated, this should be done rather than to let the handicap remain and undertake a vocational rehabilitation. It is also evident that until everything has been done to put the disabled person in the best physical condition, any steps for vocational rehabilitation may be premature and unwise. It seems, therefore, that while the new state systems of vocational education and placement for disabled persons are necessarily an educational and social welfare activity they must secure the most complete possible interrelation with the work of physical restoration.

In the opinion of not a few who are engaged in the work, a physical examination of every applicant for vocational rehabilitation is essential, first in order to determine the extent of the handicap, and second, in order to determine whether any physical restoration is possible, and if not, whether the applicant is physically able to perform the duties of the occupation chosen for him. Those who wish to keep the rehabilitation work as free from needless routine and formality as possible do not agree that an examination should be made in every case but admit that it is necessary in a large number of cases.

If physical rehabilitation then is not the direct charge of the state vo-

cation rehabilitation system, whose concern is it? This cannot be answered without making an analysis of the various classes that are covered by rehabilitation. The movement as it is now being conducted in this country cares for some widely divergent groups. The first demand for the work was made on behalf of the persons disabled by injuries within the scope of the workmen's compensation acts. It was soon seen, however, that if it was worth while for the state to establish machinery for reclaiming any group of disabled citizens, it would be sound public policy to use the same machinery for all who were handicapped. As a result the present scope of the system includes victims of all other industrial accidents, of non-industrial accidents and of disease. The great variety of cases must make it very doubtful to anyone whether a single solution of the problem of physical care can be found.

## Large Number of Injuries

Let us consider the workmen's compensation cases first. Here one is on firmer ground. Surely, with the progress that has been made by this admirable social insurance plan throughout the country, no one would advocate a new system for physical rehabilitation in the compensation cases. It is true that the care given and the standard fixed by many state laws is very inadequate, but the remedy lies in perfecting the system, not in replacing it with a new one. Every state compensation law should provide full medical, surgical and hospital care necessary to cure and relieve from the effects of the injury. It should include proper prosthesis as a part of such care. It should set up such efficient state supervision of the medical care given under the act that the best results would be attained. If there were a reasonably complete medical report filed on each compensation case and reviewed by a competent medical officer of the administrative body, the benefit from the suggestions alone that could be made as to improved treatment should be very great, to say nothing of such steps as clothing the administrative body with power to step in and order a change in treatment in cases where it seemed necessary.

The statistics that any state can disclose of the large percentage of

permanent partial disabilities that are made up of impairments instead of dismemberments would suggest to the layman that here is a place where a big improvement could be made. Illustrating this by the Minnesota statistics which are at hand, I find that out of 1,176 permanent partial compensation cases closed in the year ending June 30, 1920, 613 were cases of loss of function compared with 563 that were dismemberments. The dismemberments include amputation at any time after the injury, and it is possible that even in this group there are some that can be saved by improved methods.

In the absence of effective state control much could be done by voluntary action on the part of the insurance companies. It is not meant to be implied that any of these are not now giving a very high grade of medical care, but it is felt that this is a field where the insurance companies might well be at competition to show which can render the best service. At the San Francisco meeting of the International Association of Industrial Accident Boards and Commissions, a representative of the insurance companies expressed the thought that they should have a place in the rehabilitation movement and that this place should be given them by such changes in the laws as would make it possible for them to reduce compensation if they effected rehabilitation. The writer opposed this view, holding that reduction of compensation in such cases would penalize the injured man and would be a deterrent to rehabilitation. He offered as an alternative the suggestion given above, that the insurance companies had their place in rehabilitation because they have so much to do with the physical restoration of the injured man. Their incentive to do well in this field should be that of service and the time should come when an employer would pick an insurance company because of its reputation for giving the best service in rendering the injured man physically fit.

When one turns to the non-compensable disability cases the difficulty of a uniform plan for the entire group continues. This group can be divided into a large number of classes none of whom have any features in common. One of the important classes is made up of the injured railroad em-

ployees. Adjustment is usually made with these on the basis not of a workman's compensation law, but of a modified liability law. The question of negligence continues and in many cases no financial relief is received. As a rule, railroad companies cooperate in maintaining benefit fund systems for their employees, and medical and hospital care is a feature of such systems. It is clear again that in dealing with these cases the state rehabilitation system can act in an advisory capacity only. Nor is the problem any simpler in the other classes which are covered by the group under consideration. Some of these classes are farm accident cases, traffic accident cases, tuberculous cases, disease cases of various kinds and congenital cases.

While it is possible that a state which would create a system for physical rehabilitation in conjunction with or subsidiary to the vocational rehabilitation system and with the design of serving as a catch-all for such cases for whom no other provision existed, would find that it could accomplish much good, it would also discover that it required very careful management in order to keep it from interfering with the growth of other specialized provisions which have more warrant for existence. There are so many difficulties to be encountered in setting up standards as to where private medicine ends and public medicine begins that it would seem to be the part of caution to approach this aspect of rehabilitation slowly.

On the whole, therefore, it would appear that sound policy dictates an advisory relation to physical rehabilitation upon the part of the vocational rehabilitation system rather than a relation of direct management. It should be the function of the vocational rehabilitation system to understand all the existing provisions for physical care and bring the injured person in touch with the proper agency for treatment or prosthesis at the proper time. In other words it should make itself a center of influence with respect to physical rehabilitation. It should place itself in a position to know what should be done and also as far as possible, bring the right forces into action. Only in exceptional instances will its own direct work be also therapeutic. At times, there will be cases where the disabled person will begin a course of vocational training at some stage of his convalescence and the course will serve at the same time as occupational therapy. In the great majority of cases occurring in civil life, how-

ever, the disabled person is likely to postpone his entrance upon a course of training until he is beyond the need of medical treatment and until various factors affecting his future plans, such as compensation, damage, maintenance funds, or the like, are definitely determined.

The relation just outlined for the rehabilitation system will not be found to be a narrow one. It has not been so found in Minnesota. It offers scope for abundant activity, much accomplished, and the gradual development of policies which will eventually fill the gaps in the provisions that now exist.

### Adequate Diet is Egyptian Government Study

At the request of the Department of Public Health of the Egyptian Government an investigation has been carried on during the last three years by Dr. W. H. Wilson, professor of physiology at the Cairo Medical School, into the nutritive value of the rations issued to officials and employees in the various administrative departments, the results of which have now been published by the Department.

Fifty-seven groups of individuals are given distinct ration scales of which 38 receive full daily rations. Dr. Wilson takes Prof. E. H. Starling's "ordinary work diet" of protein 100, fat 100, and carbohydrates 500 g., as a standard, though with some doubts as to the protein sufficiency "unless it contains the proportion of animal protein generally present in the diet of well-fed Europeans." This depends entirely on the quality of the protein, which he terms its biological value—that is, the relative proportion absorbed. He instances a convict diet "for light labor," with a gross protein of 110.6 g. and a (protein) biological value of 33.5 as compared with a Waqfs Hospital ordinary diet containing protein 83 g., with a corresponding value of 50.2. In the former, the protein is entirely of vegetable origin, except for 6.3 g. derived from meat; in the latter there are 70 g. meat (without bone) and 200 g. milk, also 60 g. cheese, these three items contributing 35.5 to the total 83 g. gross protein. With regard to fat, Dr. Wilson would "suggest tentatively" that "the minimum for any (adult) diet should not be less than 30, for light work 35, and for moderate or 'hard' labor 45 g. daily."

Stress is laid on the importance of a proper distribution of nutritive

value in the various meals, especially in regard to breakfast. In prison diets the breakfast at 5:30 a. m. consisting of bread contains 22 per cent of the total food value. "It is physiologically unsound that adult men should be engaged on heavy labor for six hours on so small a ration, especially as the meal contains no fat." In the school diets for girls, breakfast contains 24 per cent, and in those for boys 27 per cent of the total calorie value; but in those for schoolmistresses and at the school of domestic economy, the breakfast contains only 19.6 and 19 per cent respectively and some improvement is desirable.

Many other points are dealt with in the report which should be of value to all concerned with dietary matters in tropical and subtropical countries; the actual food quantities contained in the dietaries of schools, training colleges, hospital asylums, and prisons, and for soldiers and sailors, are given in detail together with a comprehensive series of chemical analyses of the food articles supplied with an estimate of their dietetic value in a series of over 60 tabular statements.

The Society of American Bacteriologists at a recent meeting in Philadelphia appropriated a fund for a research fellowship in pure bacteriology. The society believes it the duty of bacteriologists to fill the gap in the knowledge of fundamental principles which is chiefly due to the fact that most of the worthwhile work being carried on at the present time deals largely with the practical application of bacteriology. The following committee is in charge of selecting the fellow, supervising the work, approving the problem selected, and passing upon the thesis submitted as the report of the research:—Dr. Victor C. Vaughan, National Research Council, chairman; Captain C. S. Butler, Naval Medical School; Dr. Geo. W. McCay, U. S. P. H. S.; Dr. John R. Mohler, Bureau of Animal Industry; Mr. L. A. Rogers, Bureau of Animal Industry; Col. Jos. F. Seler, Division of Sanitation, U. S. A.; Dr. Erwin F. Smith, Bureau of Plant Pathology.

Women of the New York State Reformatory at Bedford are on the average of a lower grade of mentality than are the men of Sing Sing prison, statistics show. Psychiatric tests of the arrivals at Bedford show an average mental age of ten years; while Sing Sing prisoners show an average mental age of 13 years, 2 months.

# Recent Compensation Decisions

By DOROTHY KETCHAM, DIRECTOR SOCIAL SERVICE DEPARTMENT,  
UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Supreme Court of Michigan, March 30, 1922, held that death resulted from an "accident" within the Workmen's Compensation Law in the following case. The Industrial Accident Board says in part:

For a period of about eighteen months Otto Klein had been employed in manufacturing automobile parts and batteries. While dipping parts of batteries in sulphuric acid and caustic soda he spilled the solutions on his hands, arms and legs, causing sores on his wrists and legs. He worked in what was known as the vat room where there were fumes from the sulphuric acid, which were injurious to decedent's health and caused him to suffer from a toxic and nervous condition. . . . On January 3, 1920, while putting a radiator in place in a hole on the second floor of the plant . . . he accidentally let the radiator slip through the hole, and it fell, striking a man . . . on the head, causing a wound and rendering him unconscious. . . . There is testimony to the effect that the shock was so great that it affected Klein, and that he continued in a highly nervous state and condition from that time on, and that at night he would wake up and cry out that he had killed this man. He continued his work four days after the accident, when he was taken to his bed in a delirious condition, which delirious condition continued and grew worse until the 15th of January, when he died. . . . Under the medical testimony before us, it is established that death resulted from the shock, which the decedent experienced from the accident of accidentally permitting the radiator to fall, hitting his fellow workman and injuring him.

The question before the court is: "Did Mr. Klein come to his death by reason of an accident within the meaning of the Employers' Liability Law?" In the instant case Mr. Klein could not anticipate that, when he removed the register, it would slip from his hand, nor could he anticipate it would hit a fellow employee, rendering him unconscious, nor could he anticipate that he himself would receive a shock which would so affect him in his weakened condition that he would as a result thereof, pass away in less than three weeks. This, however, was just what happened, in the opinion of the attending physician and the other doctors. This was also the conclusion of the Industrial Accident Board. The findings of fact made by the Industrial Accident Board acting within its power are, in the absence of fraud, conclusive. The

award was affirmed.—*Klein v. Darling Co.*, 187 N.W. 400.

DISABILITY from disease, either caused or accelerated by an occurrence in the cause of employment which is an accident, is compensable under a decision of the Supreme Court of Utah, April 8, 1922. The industrial Commission made an award and the case came before the court upon a writ of review. The findings of fact are stated briefly. On January 17, 1921, Clarence Snyder, a carpenter in the employ of the Tintic Milling Company, was ordered with another employee to remove or change a bulkhead in a flue that carried the fumes from the roaster.

When they first attempted to enter the flue, the fumes were so strong they could not go in, and had to wait about half an hour. Then they went in and removed the bulkhead, whereupon the applicant became sick. . . . He continued to work, however, for a period of three days, during which time he continued also to cough, and kept getting worse. . . . With the exception of the first three days thereafter, he was never able to work at his regular employment.

Expert medical opinion was to the effect that before January 17, 1921 the applicant was afflicted with pulmonary tuberculosis, and that the alleged accident of January 21 had little or nothing to do with the injury of which he complained. He admitted that the occurrence might have aggravated or accelerated the disease, but it was by no means the starting point.

The Court is of the opinion that there is ample evidence in the record to sustain the findings of the Commission that the injury was either caused by the occurrence of January 17, or that said occurrence lighted up a dormant condition which previously existed as found by the Commission.

What is termed an accident must be something out of the ordinary, unexpected, and definitely located as to time and place. If an injury is incurred gradually in the course of employment, and because thereof, and there is no specific event known as the starting point, it is held to be an occupational disease, and not an injury resulting from accident. . . . Being convinced . . . that Clarence Snyder, the employee in this case, on the 17th day of January, 1921, at a definite time and place, while in the course of his employment, received an injury by inhaling gas, wholly unexpected by him, and that

such injury aggravated and accelerated a pre-existing disease and rendered him wholly unable thereafter to continue his usual employment, I am of the opinion that the findings, conclusions and award of the defendant commission should be affirmed, with interest on payments past due, at plaintiff's costs.—*Tintic Milling Co. v. Industrial Commission of Utah*, 206 Pac. 278.

THE pleadings were faulty and the following case was set aside for new trial by the Court of Appeals of Kentucky, May 19, 1922. The only point to be particularly noted is that where a petition alleged that a coal company negligently failed to construct proper air courses or to provide its mine with means of ventilation required by law and permitted poisonous gases at a place of employment of the plaintiff, by which his lungs and system became contaminated, and he became weak and ill, and was compelled to discontinue work for fourteen days, was good in the absence of a demurrer or motion to make it more specific, insofar as it sought recovery for the time alleged to have been lost.—*Kentucky Elkhorn Coal Corporation v. Bingham*, 241 S.W. 60.

AN employee of a shipbuilding and repairing company, while engaged in the discharge of the duties of his employment, received an injury and died. Shortly after the death, the widow entered a claim for compensation which was denied after a hearing by the Industrial Accident Board of Texas. Mrs. Schrieber alleged, substantially that her husband, while engaged in the performance of his duties as an employee, fell from a scaffold which was constructed alongside of one of the boats on which he was working into the shallow water under the boat, and in such fall sustained injuries which caused his death. The insurance company carrying the policy of insurance under the Workmen's Compensation Act filed a general demurrer and general denial, stating that death was caused by cerebro-spinal syphilis, and upon such ground denied liability under the policy.

The case was tried and an award was made, a motion for new trial being overruled, an appeal was taken to the Court of Civil Appeals of Texas, November 14, 1921, April 17, 1922. A rehearing was denied May 3, 1922. The trial court's judgment was referred in some particulars and affirmed.—*Millers Indemnity Underwriters v. Schrieber*, 240 S.W. 963.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Air-Conditioning, Longevity, and Health

Temperature and Humidity Regulation Is Health Factor in Home, School and Factory

BY W. DWIGHT PIERCE, PH.D., SAN MATEO, CAL.

THE average educated person asked to tell through what agencies death and sickness dealing organisms may reach the human body might correctly include as the principal agencies air, food and drink, exposure and accidents.

The bearing of the whole subject of air conditioning upon life and accident insurance is enormous, and doubtless industries which base their working conditions upon scientific principles will find after the trial periods are past that from all insurance viewpoints their employees are better insurance risks than they had been before.

The science of air-conditioning has had its rise through several distinct agencies. Through the sanitarian we have learned the importance of fresh air and ventilation in shop, factory, and home, and something about its regulation. Through the medical profession we have learned the importance of climate and fresh air in the cure of certain diseases. Through the manufacturers we have learned that their products are better and their machinery works better at certain times of the year than at other times. The engineering profession has met this industrial problem by solving the problems of thermostatic and hydrostatic control of factory conditions. The biologist, working on his insect problems, has learned the relationship of temperature and humidity to insect development and activity, and has applied the principles thus derived to other types of life and finally to man. The results of combining these findings of independent branches

of research into a real science of air conditioning are incalculable.

One of the sanitary requirements set down for public buildings and factories was a maximum limit of carbon dioxide in the air. Unfortunately we have been slow in learning significance of the physical characteristics of the air, and the sanitarian still has a definite problem before him as regards this specification. For it is now known that the volume of carbon dioxide which can be held by the air without prejudice to the human system is dependent upon temperature and relative humidity, and this latter in turn is dependent upon atmospheric pressure. Thus it appears that new studies must be made to correlate the gas constituents of the air with the physical characteristics of the air.

While these fundamental laws of permissible gas are being worked out we are not without means of profiting by the general principles involved. We know that too much carbon dioxide is not good. We know that the human being needs oxygen. While the experts are determining the safety margins beyond which none should transgress, let us look to obtaining a sufficient amount of fresh air through ventilation so that we shall always be safely within the limits. There are many systems of ventilation, more or less effective, and experienced engineers are constantly improving the types of ventilation. The sanitarians have time and again furnished detailed examples of definite gains in human efficiency brought about by satisfactory ventilation. The medical

profession has established beyond a doubt the therapeutic values of fresh air in hospital and home.

The first law of air-conditioning may be stated as follows: For every living creature, plant and animal, there is a condition of the air as regards its gaseous composition of oxygen, carbon dioxide, and other gases, all other things being equal, at which the particular species of plant or animal thrives best, and as the composition of gases departs from the optimum condition the welfare of the species diminishes until a point is reached in which life is impossible. This law must be applied separately for each species and race, for divergence from type as regards gas resistance is one of the factors in the creation of races and species.

The science of air-conditioning, however, only begins with the thought of fresh air. The reason for ventilation is chemical and physiological. We must supply the lungs with plenty of oxygen to purify the blood; we must remove the waste products which are thrown off from the lungs.

There is reason to believe that there are certain physical conditions of the air under which human efficiency is greatest when the constituents of the air are proper. The air has several physical characteristics which are of utmost importance in this study.

The first of these is atmospheric pressure or the weight of the column of air above us. Those who have been up in high mountains realize how the lightness of the atmospheric pressure weakened them. They were

unable to obtain sufficient oxygen in the rarified atmosphere; the heart fluttered; they quickly wearied. As they went down they became more and more invigorated. But in like manner those who have descended into mines have felt the increased pressure until to go farther was to endanger life.

The second law of air-conditioning provides that for every living creature, plant and animal, there is a weight of atmospheric pressure, all other things being equal, at which the particular species of plant or animal thrives best, and as the atmospheric pressure departs from the optimum the welfare of the species diminishes until a point is reached in which life is impossible. This law must be applied separately for each species or race, for divergence from type as regards atmospheric pressure is one of the factors in the creation of races and species. This law is fully illustrated in the Life Zones on a high mountain.

The third law of air-conditions states that for every living creature, plant and animal, there are a quantity and quality of light, all other things being equal, at which the particular species of plant or animal thrives best, and as the quantity or quality of light departs from the optimum the welfare of the species diminishes until a point is reached in which life is impossible.

The third physical characteristic of the atmosphere has to do with those low vibrations in the atmosphere known as heat waves, in other words, temperature. It is the custom to speak of air conditions in terms of temperature and to describe sensation in terms of warmth and coolness. "This has been correct in a sense because sensations are due to certain attributes of the temperature. Nevertheless there are many people who cannot understand why they are likely to collapse when the thermometer stands at 90 degrees in New York and can play tennis at 110 degrees in Dallas or Phoenix. They do not see why they should feel exhilarated in Denver at 32 degrees and be chilled to the marrow in San Francisco at 40 degrees. This is because they have ignored the fourth factor, humidity. Temperature was the first atmospheric factor which received much attention in the study of air effects on activity, and all early biological work was done in an effort to determine the laws of effective temperature. This work failed because the law of the optimum, and

diminished efficiency with variations from the optimum in both directions, was not understood until in 1916 the zones of temperature were defined.

The fourth law of air conditions is similar to the others: For every living creature, plant and animal, there is a degree or zone of degrees of temperature, all other factors being equal, at which the particular species of plant or animal thrives best, and as the temperature departs from the optimum the welfare and activity of the species diminishes until a point is reached in which life is impossible.

### The Humidity Factor

The factor of humidity is just as vital to life as temperature, although it has been greatly neglected or misunderstood in past studies. Relative humidity is the percentage of saturation of the atmosphere with water vapor. The quantity by weight of water vapor which can be absorbed by the air depends upon the atmospheric pressure, the temperature, and the gaseous content of the air. Many investigators have studied humidity from the standpoint of the weight of the column of atmospheric moisture, or by the dewpoint, or the temperature of the wet bulb thermometer, but none of these mathematical units gives us the opportunity to make a good comparative study of reactions, such as is possible with relative humidity. Using this quality of the air the fifth law may be framed: For every living creature, plant and animal, there is a percentage or zone of percentages of relative humidity, all other factors being equal, at which the particular species of plant or animal thrives best, and as the relative humidity departs from this optimum the welfare and activity of the species diminishes until a point is reached in which life is impossible.

It is apparent from the foregoing that when we speak of proper air-conditioning, even for human beings, we cannot speak exclusively in terms of ventilation, of temperature, of humidity, or of light, but that what we are seeking is a condition in which all of these factors and the uncontrollable factor of pressure are concerned. The problem then deals with a combination of factors on different planes, as it were, all reacting in the same general sort of way and we can very well conceive of the air conditions as a sphere cut in different directions by the planes of the factors which affect life, the heart of which sphere is located in those zones of light, heat, moisture, pressure, and gas which

are most favorable to development, activity, and efficiency, and surrounding which are concentric layers of condition less and less favorable to the welfare of the species, until on the outside of the sphere are found the conditions absolutely inimical to its life.

The sixth law is that for every living creature, plant or animal, there is a combination of quantity and quality of light, atmospheric pressure, quantity and quality of constituent gases, temperature, and percentage of relative humidity, at which the particular species of plant or animal thrives best, and as any of these factors depart from this optimum the welfare and activity of the species diminishes until a point is reached in which life is impossible.

The biologist knows that the higher plant and animal species are merely assemblages of living cells grouped into organs and systems of organs and that therefore what affects the body as a whole affects its constituent parts, and what affects the constituent cells affects the whole body. We then proceed to our seventh law which is very important in the question of treatment of disease. For every living creature, plant or animal, and for every cell and organ and part of such creature, at no matter what stage of development, there is a combination of the atmospheric factors of gases, light, heat, pressure and moisture at which the life functions of metabolism, assimilation, transpiration, growth, reproduction, etc. are at their greatest efficiency. This combination or zone of conditions is called the *Practicotatum*. By greatest efficiency we do not necessarily mean capability to do the greatest amount of work, but rather the capability to do the greatest amount of accurate, dependable work, with the least exhaustion, wear and tear.

Before coming to a discussion of the bearings of all these laws on human life and happiness and the prosperity of those who apply them, we must bring out one more law which is of utmost importance to all business men and especially to manufacturers. In the textile industry, the rubber industry, bread making, candy making, macaroni manufacture, ceramic industry, and in the making of many kinds of machinery, it has already been proven beyond contradiction that regulation and uniformity of temperature and humidity are necessary for perfect production. Behind all this is the fact that the chemical world also reacts to all

these air factors in a similar manner. The eighth law may be stated as follows: All forms of life, plant and animal, microorganisms and complex organisms, and all kinds of machinery, metals, and chemicals and all products of manufacture are affected in the same general manner by the factors of the atmosphere, gases, light, pressure, temperature, and humidity, in that in each case there is a combination of these factors at which they are at their best, and divergence from which results in reduction of efficiency or quality or some other desirable characteristic.

Inasmuch as every function of the human body and every portion of the body is governed more or less in its reactions by the conditions in the air about us, it is directly incumbent upon us to see that we have opportunity to live and work under such conditions that our health may be best, our lives longest, and our work most productive. It is also both our duty and our interest to see that conditions are such that those who work for us shall also have like opportunity. Furthermore, it is a function of the state to see that no person shall be forced to work under conditions inimical to health and by regulation, also to secure for the worker the best possible working conditions.

The same principles are acting upon our well being at home, at church, in the theater, in the trains, as in office and factory. Many a laborer works eight hours under fairly hygienic conditions and then at home incloses himself in an atmosphere that undermines. Many another laborer lives at home in a fairly hygienic manner and during his shift is subjected to air conditions which quickly take away his vitality. We are concerned here with laws that operate twenty-four hours of every day in the year throughout our lives.

A few of the important features of air effects on man will be brought out in order that we may grasp the significance of the whole question and see the direction in which practical application must be made. We are far from knowing all the facts as regards man—in fact we are just beginning to learn them. Therefore, such figures as shall be given regarding zones of reactions are more or less approximate only.

The average human praeticotatum or comfort zone (if we count only temperature and humidity and consider all other factors as equal) may be charted as an ellipse with the axes diagonal, and bounded by 32 per cent

and 55 per cent relative humidity, and 55 degrees and 70 degrees F. mean temperature, with the center at 63 degrees F. and 43.5 per cent humidity. These conditions are ideal at the average atmospheric pressure of 30 or 31 inches, when the air is fresh and the light satisfactory. If we could maintain our living and working conditions within this zone we would accomplish the greatest amount of effort.

Surrounding the zone of comfort is a larger zone of temperature and humidity in which we are still able to do effective work and the most favorable conditions are those nearest the center. This zone extends for the average man from 36 degrees to 90 degrees F. temperature and from 2 per cent to 85 per cent relative humidity. It is elliptical in form, so that 90 degrees F. and 85 degrees humidity would be far outside the zone. We shall illustrate this in a moment. Man is quite an adjustable creature and can work under many different conditions, even outside this zone. But in general within its limits he works without excessive exhaustion and without great increase in bodily temperature. His comfort is more or less governed by the nature and weight of his clothing, his previous adjustment to the given working conditions, the nature of his food, and the amount of the physical energy required. The person sitting all day needs a higher temperature at a given humidity than one exercising. We may call this the zone of practical working conditions, and broadly speaking no man should be expected to work, except for very short periods under hygienic factory conditions, at humid-temperatures outside this zone. An easy way of determining whether one is outside the zone as regards humidity is by reading the wet bulb thermometer, which should not be higher than 70 degrees F. at 30 inches pressure. The wet bulb thermometer is one of a pair of equal thermometers, one of which has the bulb covered with a cloth cap and wet. These are whirled until there is no change in the readings and then the wet and dry bulb readings are read from which humidity can be figured.

We should keep our home temperatures and humidity between 63 degrees and 68 degrees F. and the humidity between 40 per cent and 43 per cent, but never below 32 per cent nor above 55 per cent at these temperatures. If 70 degrees F. is desirable, then the humidity should be

37 per cent to 40 per cent. In the heating of houses the temperature is too apt to go above 70 degrees and the moisture is often entirely exhausted and the air stale with carbon dioxide. With a dry heat of any kind, unless the ventilating air is very moist, some means must be used to restore moisture to the air. This is often done by heating a broad topped vessel of water or a tea-kettle.

Hospitals will no doubt apply these principles to the treatment of their patients, keeping them under the condition most favorable to the curative processes and least favorable to the multiplication of the disease organisms. Office managers will seek to establish the point at which the mental activity of their clerks is most alert and accurate and will maintain this condition throughout the year. Managers of theaters and assembly halls, trustees of churches, will desire to know the conditions under which their patrons are most keenly appreciative of the entertainment or services rendered. Factory managers will seek to reconcile these zones of factors so that they may obtain the best quality of product obtainable, with the greatest efficiency of production by the machinery, under the most suitable conditions for human efficiency.

It is very important while still discussing the zones of working conditions, to point out that man is a variable species, of many races, and that the different races of men have become so long inured to certain ranges of temperature that the bodily metabolism has adjusted itself thereto, and consequently when we bring together men of different races, or of a different climatic upbringing, we can not expect them to react alike to the conditions we fix until their metabolic functions have accomplished the change which we call acclimation. We can use this fact to advantage by assigning men able to stand high temperatures to the tasks which necessitate conditions unsuitable for the average person, and in like manner we can sort out the workers for the cold, the wet, the dry tasks.

Surrounding the zone of practical working conditions are more or less concentric zones and subzones of reactions such as those of debilitation and discomfort, sluggishness, pain and intense suffering. Work can be done under such conditions but is accompanied by some of the following sensations: chill, numbing, thirst, parched sensation, excessive perspiration, stifling, depressing fatigue, fre-

quent need of rest, quickened or sluggish pulse, fever. These conditions should be avoided in any place of work if possible, for the workman subjected to them is not only in danger of his health breaking down, but his efficiency is greatly reduced and his mistakes, errors and breakages are greatly increased. It pays to take account of the comfort of employees because when they are uncomfortable profits are reduced and losses are increased. Under no conditions should hospital patients be kept under any of these conditions.

Surrounding these subzones of discomfort and pain is the zone of sleep which merges into the outer zone of death.

As examples of the fact that the axis of our figures is diagonal we may take the line of 80 degrees F. At 80 degrees and 20 per cent humidity one experiences no discomfort in work; at 65 per cent humidity discomfort is felt; at 80 per cent rest is necessary; at 100 per cent hard work is impossible. Even at 70 degrees one may work without discomfort from 2 per cent to 75 per cent humidity, and with greatest comfort at 40 per cent humidity; at 85 per cent

there is comfort only when quiet; and at 91 per cent depressing fatigue is experienced. But at 90 degrees temperature the only humidity at which one is likely to experience no discomfort is about 25 per cent, while at 50 per cent it is considered in the textile industry that operatives should not be required to work; at 65 per cent hard work is impossible; at 81 per cent the body temperature rises when one is at rest; and 90 per cent is dangerous to the health; while at 100 per cent fever and death may occur. Fatalities from heat at 5 per cent humidity occur above 115 degrees; at 20 per cent above 119 degrees; but at 100 per cent may occur at 89 degrees.

Air conditioning was first brought about by the demand for better quality of products and less injury to the product in the textile industry, and later utilized in many industries. The engineering profession has solved the problems of automatic regulation and control of temperature and humidity, so that by thermostat and hydrostat a fixed combination of conditions can be maintained indoors, no matter what the conditions outdoors. A complete installation involves equipment

for ventilation or air washing, humidifying, dehumidifying, heating and cooling, and of course our last requirement is proper lighting. All of these things can be accomplished by the engineering profession at costs which make them feasible in most factories.

The principal point is that after the installation of an adjustable system capable of regulation to a very small margin of variation, the conditions under which the system must be operated in a given plant have yet to be determined. The determination of the conditions necessary in each department is one for the efficiency engineer, who will study the biological requirements as well as the requirements of the equipment and product. Each department may ultimately be operated under entirely different air conditions. The application of these principles in business, in the home, the auditorium, the hospital, will result in greater health and happiness, greatly reduced incidence of colds, fevers, and lung diseases, more efficient hospital treatment of disease, and naturally greater longevity to those benefitted by living and working under proper air conditions.

## Some Problems in Unscientific Living

**R**USSIA has seized and expelled from her borders for varying periods fifteen hundred intellectuals and scientists as non-essential if not undesirable citizens. The situation offers interesting vistas for speculation.

As a remedy for the many evils of present modes of existence the expedient of returning to the simple life is often suggested. The expulsion of scientists offers a quick and sure way of accomplishing this. If, for instance, as may easily be conceived, the body of expelled experts included bacteriologists, scientific methods in the handling of communicable disease would at once reduce preventive medicine to the clumsy expedient of absolute isolation of every one affected with contagious forms of disease. Utensils, clothing, and other means of contact might under such a regime be sterilized by boiling, but without the voice of science this would scarcely be considered necessary. There would naturally result a much higher death rate from a wide range of disorders, which would be all to the good if microbes had the habit of taking off the undesirables only; but, as conta-

gion falls impartially upon the genius and the dullard, survival under such conditions would be to the lucky and not necessarily to the fit.

Not only in the practice of medicine would commonplace, untrained direction of affairs cause a slump in standards. Without our engineers all the commoner comforts of life would be subject to change. Community water supplies would give way to the common well or the contaminated stream. Urban communities would of necessity be dispersed as the scientific solution of collective problems became impossible. Electricity, harnessed and made to serve practical purposes only by experts, would yield to sources of power utterly unsuited to our present requirements. Communication would fall off and those arts which are perfected through interchange of ideas and through cooperative effort would fall into disuse. Even the reactionaries who bemoan our transition from the day when the craftsman was identified with his own individual product would face with fear the change of economic regime to the drudgery and abuses of old systems of apprenticeship and to the home workshop

where there was little need for the worker to produce more than would meet his own individual needs, and when the standard of his work was not higher than the immediate copy he followed. Far more than is generally appreciated our standards of living are the outgrowth of specialized services of one kind and another, and it is scientific imagination which affords the ideals that spur men on to creative effort.

For the common people life would be miserable indeed. Our homes would be unlighted, unventilated, unplumbed; habits would need to be altered on the basis of primitive sanitation—if in fact sanitation is possible at all to primitive thinking. Let us promote, therefore, every agency for making the scientific solution of our daily problems a common objective and a daily habit. Especially is it necessary to get together on community health problems. Each community should consider its own specific health problems during Health Week, set for October 23 to 30, which is an opportune get together health effort on the part of both professional and lay workers.

# Scoliosis Prevention During School Period

## Examination of School Children Will Do Much to Offset Deformity

BY ARCHER O'REILLY, M.D., F.A.C.S., St. Louis, Mo.

**S**COLIOSIS is one of the most interesting problems in orthopedic surgery because it is unsolved. Almost every orthopedic surgeon has devised some method of treatment or has contributed some thoughts on its cause or mechanics, but as yet, no cure has been devised. The deformities in structural scoliosis tend to increase and, unless prevented, may become very marked and unsightly. As correction has not been successful, prevention is most important. It is this latter phase that I wish to emphasize particularly in this paper.

Scoliosis is a common deformity. Whitman says that it comes next in frequency to bow legs, and Bradford and Lovett state that it is found in between twenty and thirty per cent of school children. It will be seen from this that scoliosis is an important deformity and one that should be taken much more seriously than it seems to be at present, especially when one considers the amount of the deformity and the difficulty of correction.

There are two types of scoliosis: (1) the postural or total curve, a long sweeping curve from the neck to the sacrum, usually the result of weak musculature or faulty posture; in this type there are no bony changes; (2) the structural curve, composed of two or more curves, in which definite bony alterations have taken place.

The simple postural curve is less serious and can be fairly easily corrected by gymnastics, by postural exercises, and by the use of a light support such as a brace, a leather or celluloid jacket. The postural curve is of importance, however, and in no case should it be neglected because it may very readily develop into the structural curve. The structural curve is difficult to treat, and once it has developed its correction is almost impossible. For that reason it is most important that it should be prevented or its development be arrested at the earliest possible moment.

In order to emphasize the importance of structural scoliosis some of the changes that take place will be reviewed briefly. The structural curve is always compound. As the spinal curve develops, changes take place in the vertebrae, especially in the

bodies. These become distorted and wedge-shaped, compressed on the concave side and expanded on the convex side. Coincident with the development of the curve, the bodies of the vertebrae rotate from the mid-line toward the convexity of the curve. Rotation is always present in structural scoliosis. There are many theories and explanations offered to account for rotation. Three of the more prominent ones are: (a) If an elastic rod curved, say, antero-posteriorly, is bent laterally, it twists on itself. The spine is a rod of this type and acts similarly. (Lovett.) (b) The ribs on the convex side are expanded, stretching the muscles, which cause an elastic pressure that is transmitted posteriorly to the rib attachment, so causing the vertebral bodies to rotate in the opposite direction. (Feiss.) (c) The body weight acting through a laterally curved spine may be split into two components, one tending to displace further the vertebrae to the convexity of the curve. The brunt of the body weight is borne by the column of the bodies which are therefor displaced more than the unweighted and muscularly held arches and processes. The net result—that the bodies tend to displace while relatively the arches do not, is that convex rotation is set up. (Tubby.) This later theory seems to be the more plausible, especially when one considers that compression takes place on the concave side and expansion on the convex side, rendering rotation on that side more easy.

Rotation is a serious and marked deformity. The ribs are carried backward, the angle becomes sharp, resulting in a most unsightly prominence. The thorax is flattened on the side of the curve. The treatment is directed at the correction of the curve and the reduction of the rotation. It is this latter phase of the deformity that is so difficult to correct and that renders treatment so unavailing. The great number and variety of methods suggested are proof of our failure to devise, as yet, a satisfactory method of treatment.

The best method of treatment, I believe, is by the plaster of Paris jacket. The spine is corrected as much

as possible and a jacket applied to hold it in that position. In about six to eight weeks the jacket is removed, the spine is further corrected, and another jacket is applied. This is repeated until no further correction can be obtained. When the spine is as nearly corrected as possible, a removable jacket may be worn and gymnastic exercises given to strengthen the back. I do not believe that, in the majority of cases, braces are of any value in the treatment of scoliosis. They can easily get out of adjustment and the patient must be under constant observation, and unless the brace is constantly exerting a corrective pressure, it is worse than useless. Some orthopedic surgeons claim to have obtained good results with braces, but they are the exception.

Prevention, then, is most important, and every effort should be made to detect scoliosis in its earliest stage, and by proper treatment cure the deformity or at least prevent its further development. In order to accomplish this end children's backs should be frequently inspected. From an experience in an orthopedic clinic where many cases of scoliosis are seen each year this does not seem to be the case. The usual history given, is that the parents have suddenly noticed a lump on the patient's back, or that while bathing the child, they noticed the scoliosis. In most of these cases the deformity, when brought to the clinic is quite markedly developed, with well pronounced rotation. Another history frequently given is that when the patient was being fitted with a dress the dress-maker noticed that one hip was larger or that one shoulder was lower than the other. All of this shows a lamentable lack of observation on the part of the parents and an ignorance of the seriousness of the condition. But it is ridiculous to expect the average parent to be able to detect the early stage of scoliosis, especially when the curve is slight and practically no deformity present. In older children who are able to care for themselves, the parents very rarely have an opportunity to examine the backs, so that it is quite easy for a deformity

to reach marked proportions before it is noticed.

What, then, should be done to prevent the development of scoliosis? In the author's opinion this is a question which should be handled by the schools. In many communities there are organizations of the parents that have meetings at more or less regular intervals, and at which there are frequently lectures on various topics. At these meetings some time might be devoted to lectures on hygiene and health, and especially on the development of deformities and their prevention. Scoliosis would naturally be one of the topics discussed. The parents should be educated to demand a thorough physical examination of their children by the school physician, and if there is no school physician, then they should demand that one be employed. This seems to the author very important, because in some places the parents object to a thorough physical examination and will not allow the children to be un-

dressed, so that a thorough physical examination is impossible and the only defects discovered are those which are perfectly obvious, and those of the eyes and throat. Because of this ignorance and prejudice many children become hopeless cripples because they are not properly examined and developing deformities are not recognized early enough to be prevented.

All schools should have a regular school physician, who, in addition to looking after the general health of the children, should give them a thorough physical examination at least once, and preferably twice a year. This might take place at the beginning and at the middle of the school year. The children should be completely stripped and they should be examined for physical defects and deformities. The child's posture should be noted and also any bad habits in standing and walking. Especial care should be given to the spine to note the presence of beginning postural or structural scoliosis.

When any of these defects are present, the parents should be instructed to have them treated immediately and the danger of delay should be impressed upon them. If this routine were carried out many children would be saved from a future of deformity.

In conclusion, I wish strongly to emphasize the fact that scoliosis, even in the postural stage, is a serious condition; postural cases frequently become structural. In the advanced stage, treatment at best, is unsatisfactory and to be of value should be commenced at the very earliest moment. Patients do not outgrow structural scoliosis; in fact, the deformity tends to increase. The very best treatment for lateral curvature is prevention. To insure this, children's backs should be examined frequently. This can best be accomplished by examining all school children at least twice a year. Then if there are any signs of lateral deviation, postural or structural, treatment should be begun at once.

## Mental Hygiene and the Child\*

By C. MACFIE CAMPBELL, M.D., DIRECTOR, PSYCHOPATHIC HOSPITAL, BOSTON, MASS.

**M**ENTAL health means healthy reactions to the demands of the environment, or healthy behavior. The mechanism of behavior is very complicated and its roots go deep into the biological constitution of the individual. Behavior may be interfered with by gross disorders of the most fundamental mechanisms; it may be interfered with by much more subtle causes. In face of some problem in the behavior of the individual one has to review systematically all the mechanisms involved. The problem may be a child with chorea or bed-wetting or stammering or tantrums or morbid fears or undue dependence upon mother or pilfering or florid formation of phantasies. No matter what the nature of the reaction, the underlying mechanisms have to be reviewed. A simple symptom may have a very complex origin. On the other hand, a very complicated type of behavior may result from some simple disorder.

The physician in examining the patient lays particular emphasis on two systems: (1) on the central nervous system, and (2) on the glands of internal secretion. He also studies the general health of the individual to

see whether the reacting mechanisms may be influenced by some general infection, e.g., rheumatism, or disorder of nutrition (rickets, malnutrition), or some other physical disorder. He considers also the effect on behavior of physiological conditions, such as fatigue, and pays attention to the balance of work and recreation, the extent of sleep.

As to the central nervous system, the physician examines to see whether there is any structural disorder, such as residual from infant hemiplegia, or any less gross anomaly, with perhaps a history of epileptiform attacks. He will have to weigh the role played by any anomaly in relation to the problem for which the child is brought in, that is, he will have to consider how far the inadequacy of the child's behavior may be related to some endocrine disorder, such as a disorder of the pituitary gland.

Extraordinary changes in conduct may follow on infective disorders, such as lethargic encephalitis. The organic basis for these may be overlooked and the child treated as if liberately willful.

The physician will review the functional balance of the child as indicated by its developmental history and its reactions to the ordinary tests of

life. He will note any emotional idiosyncrasy and any special type of reaction. Children vary in their type of sleep; they vary in reaction to food. The special emotional type of the child must be considered. Behavior is not to be immediately considered willful and wayward because it deviates somewhat from the average; it may be the expression of the child's constitution, and the problem is what are the most favorable conditions for the development of the child?

Finally, the physician studies the way in which early experiences modify a child's reactions, give a special emotional value to special topics, develop special fears and likes and doubts. The physician will study the dynamic equilibrium of the various instinctive forces, and see how far the behavior of the child is to be attributed to conflicts in this sphere, and whether the conflict cannot be modified somewhat. The physician with this point of view will become very much more helpful when called to advise the parent about many of the puzzling ailments of children; he will instruct the parents that all disorders of childhood are not necessarily due to infection or to improper diet but like stomach ache, they are to be studied before treated.

\*Read Before the Forty-ninth Annual Meeting of the National Conference of Social Work, Providence, R. I., June 22-29, 1922.

# Economic Standards in Nutrition\*

By LUCY H. GILLETT, SUPERINTENDENT, NUTRITION BUREAU ASSOCIATION FOR IMPROVING THE CONDITION OF THE POOR, NEW YORK CITY.

EVERY organization as well as every individual dealing with the welfare of children should, for its most effective work, understand the economic problems involved in the family from which the children come.

The food expenditure is of vital importance, for the health of the family, and especially its nutrition, is very closely related to its food supply. If the money spent for food, or the money the family can afford to spend for food, is inadequate, the children are in danger of malnutrition, tuberculosis, and other diseases throughout childhood and perhaps they may be handicapped for life. Unless such conditions are discovered and remedied, the best nutrition program will involve much wasted energy.

In many families the income would be adequate with reasonable economy. With a better understanding of the economic factor, especially a minimum standard for safety, suggestions would be far more effective. Any individual family on a limited income needs to spend to good advantage to get all the nourishment needed by growing boys and girls. In any welfare work it is quite important to know what a minimum food allowance is. Where money is donated to any organization for distribution to provide food for families needing assistance, that organization wants to make the best possible use of the funds entrusted to it by making those funds help as many families as possible. An allowance of even one cent more per person per meal than is necessary, will increase the budget of an organization by at least ten thousand dollars for every 150 families helped.

How can we be sure that the allowance is adequate, yet a minimum, below which any family may be in danger?

The New York Nutrition Council, feeling the need for some control of this oft neglected factor, appointed a committee to standardize the method for determining what the minimum adequate food allowance is in terms of dollars and cents, and to reduce to its simplest terms the important facts in nutrition that every family and every social worker should know. There is

danger of malnutrition even when there is enough money spent for food. The food must be of the right kind as well as sufficient in quantity. Scientists have shown the very close relationship between certain types of food and health. These results show the need of certain types and a minimum of others. A diet chosen at random or in accordance with one's appetite may or may not be satisfactory.

This Committee has outlined in simple form suggestions for economical

diets which will provide adequate nourishment for children under two years of age, from 2 to 5 years, from 5 to 12, from 12 to 16, and for the adult. Weekly diets were planned to provide the proper amount of protein, fats, mineral elements, vitamins, and calories from the most economical sources so far as our knowledge allows us to suggest. All the diets presented are approved by Dr. Mary S. Rose of Teachers College. These diets are as follows:

## Weekly Diet for Children Under Two

The allowance is from 900 to 1,200 calories. Food, quantity and calories apply to all nationalities. The costs should be revised according to location and season and to admit the use of higher priced foods used by some nationalities; for example, sweet butter for salt in the Jewish diets.

Food—	Quantity	Calories	Cost in New York March, 1922— Revise to meet individual needs
Milk	7 qts.	4,725	\$1.05
Eggs	3-4	240	.12
Butter	2 oz.	435	.053
Fruit	12 oz.	350	.10
Vegetables	1 lb.	140	.09
Bread (1½ slices a day)	1 lb.	1,200	.08
Cereal (dry)	8 oz.	800	.036
		7,890	\$1.529

1,127 Calories daily—\$0.19 per 1,000 Calories

The following allowances for milk were made: For children under 2 years, 1 quart a day; for children from 2-5 years of age, ¾ of a quart a day. A quart is allowed for children from 12-16 years old because this is a period of very rapid growth. It was decided to allow bottled milk for all children under 5 years of age and for drinking for older children. Loose milk is recommended for cooking when the financial situation is such that bottled milk cannot be provided. Loose milk should in all cases be heated before being used.

## Weekly Diet for Children 2 to 5 Years

The allowance is from 1,000 to 1,500 calories:

Food—	Quantity	Calories	Cost— Revise to meet individual needs
Milk	3½-5 qts.	3,375-2,362	\$0.75-\$0.53
Eggs	3-4	240-240	.12-.12
Butter	2-3½ oz.	436-764	.053-.093
Fruit (fresh or dried, some every day)	2-3 oranges or 2-3 apples plus 2-3 oz. dried fruit	350 500	.024-.036
Vegetables:			
Green or root	1-2 lbs.	140-200	.09-.15
Potatoes	2-2½ lbs.	600-760	.08-.10
Bread	1-2 lbs.	1,200-2,400	.08-.16
Cereal	7-14 oz.	700-1,400	.032-.053

‡Eggs may be omitted when too expensive.  
‡Fat may be reduced from 1 lb. to ½ or ¾ lb.

Weekly Diet for Children 12 to 16 Years

The allowance is from 1,900 to 3,500 calories:

Food	Quantity	Calories	Cost	Revise to meet individual needs
Milk	3½-7 qts.	2,363- 4,725	\$0.53	-\$0.56*
†Eggs	4	300- 300	.12	-.12
Meat and fish	1-2 lbs.	600- 1,200	.18	-.37
Fat	12 oz.-1 lb.	2,700- 3,600	.251-	.335
Fruit	2-3 oranges	500- 750	.096-	.12
	or 2-3 apples			
	plus 3-5 oz. dried fruit			
Vegetables:				
Green or root	2½-4 lbs.	300- 650	.21	-.28
Potatoes	2½-6 lbs.	750- 1,824	.10	-.24
Legumes and cheese	4-8 oz.	400- 800	.054-	.108
Bread	2½-4½ lbs.	3,000- 5,400	.20	-.36
Cereal and flour	1 2½ lbs.	1,600- 4,000	.072-	.18
Sugar	8 oz.-¾ lb.	907- 1,360	.025-	.037
		13,430-24,609	\$1,838	-\$2,710
		1,918-3,515 calories daily	\$0.137-\$0.11	per 1,000 calories

\*The seeming discrepancy in this slight difference in milk cost is due to use of some loose milk in cooking for older children.  
 †Eggs may be omitted when too expensive.

Over 16 and Adults

The allowance is from 2,500 to 3,500 calories:

Food	Quantity	Calories	Cost	Revise to meet individual needs
Milk	3½ qts.	2,363- 2,363	\$0.53	-\$0.53
†Eggs	4	300- 300	.12	-.12
Meat and fish	1½-2 lbs.	900- 1,200	.27	-.37
Fat	12 oz.-1 lb.	2,700- 3,600	.251-	.335
Fruit	3 oranges	750- 750	.12	.12
	1 apple			
	5 oz. dried fruit			
Vegetables:				
Green or root	2½-4 lbs.	300- 650	.21	-.28
Potatoes	5-7 lbs.	1,520- 2,128	.20	-.28
Legumes and cheese	6-8 oz.	600- 800	.081-	.108
Bread	2½-4½ lbs.	3,000- 5,400	.20	-.36
Cereal and flour	2½-3½ lbs.	4,000- 5,600	.18	-.25
Sugar	12 oz.-1 lb.	1,360- 1,814	.037-	.05
		17,793-24,605	\$2,199	-\$2,803
		2,542-3,515 calories daily	\$0.124-\$0.113	per 1,000 calories

†Eggs may be omitted when too expensive.

The second part of our report summarizes very briefly the appreciation of the facts which scientists have discovered with regard to the relation between the different types of food and health. It emphasizes the need

of plenty of milk, vegetables, fruit, the grain products and fats, with a minimum of meats and sweets. These facts are stated in simple form and are called "The Fifteen Points for the Social Worker Who Has to Deal with

Keystone View Company.

In the diet kitchen the dietitian inducts the child into the fascinating art of cookery. The child's love of new experience is utilized to introduce the fundamentals of an adequate dietary to the other members of the family who do not crave to learn.

the Nutrition Problem."

The nutritional state of every child should be determined by periodic physical examinations.

(1) Fresh, clean, whole milk should be a prominent part of the daily diet of every child. Each child should have never less than a pint of milk a day, and a quart where possible. A quart should be allowed always for the undernourished and the younger children.

It is not necessary to drink the whole quart. Some of it may be taken in the form of cocoa, cream soups, simple desserts, etc.

(2) At least two vegetables a day for every child (Be sure every child eats his share). One (or two) vegetables in addition to potatoes should be eaten every day. Leaf vegetables should be used at least two or three times a week. On the other four or five days, any other vegetable may be used in addition to the potato.

Do not use soda in the cooking of vegetables.

Vegetables are abundant and relatively inexpensive in summer. When the supply is more limited in winter, increase potatoes and suggest beets, cabbage, carrots, celery, canned tomatoes, escarolle, kale, onions, squash, and turnips or other inexpensive ones. Spinach and lettuce are frequently found in the city in winter at a low cost. (Rice and macaroni are not substitutes for potatoes.)

(3) Fruit should be used (as a part of a meal) at least once every day whenever it can be afforded. When

Keystone View Company

Direct to the home the social worker carries aids to intelligent living, for the problems of living are complex and most of us need help somewhere or other in order to maintain a true perspective and to give the proper value to ultimate good as against meeting a present exigency.

Keystone View Company

The children are benefited by partaking of the food they have learned to prepare and a new appreciation of wholesome viands is awakened.

fruit is too expensive, insist on a third vegetable every day. Dried fruits are valuable but do not take the place of fresh fruit or vegetables.

All young children and any one whose chief article of food is milk should have fresh fruit or tomato juice every day.

(4) Meat is much less important than milk, fruits, and vegetables, and is more expensive. These foods should not be sacrificed for the sake of meat although a little meat is not undesirable. Meat should be limited to one meal a day and to three or four times a week is better.

(5) Cereals should be used daily. Served with milk, they are good either for breakfast or supper. They may be put into soups, or made into simple puddings, such as rice, farina, or cornstarch.

The ready-to-eat-cereals are expensive, but may be used occasionally to lend variety to the diet. They should not be used more than once or twice a week.

(6) It has been found that in families where economy is necessary, there is a tendency to eat too much sugar and too little fat. Allow at least from 3 to 4 lbs. of fat per week for every five members of the family and not over 4 lbs. of sugar.

(7) Water is an important item in the diet. Both children and adults should drink plenty of it, especially between meals.

(8) Tea, coffee, beer, or wine should never be given to children. Fried foods, except bacon, should never be given to children.

(9) A child should never be allowed to go to school without a good breakfast.

(10) Every child should have a

good luncheon with a hot dish in it—either a soup, hot cocoa, or a hot vegetable dish.

(11) Only foods of mild flavor should be allowed between meals such as bread and butter, or bread and milk, or crackers and milk. Such mid-morning or mid-afternoon lunches should be given only when the regular meals are 5 or 6 hours apart. The lunches should then be given regularly, and at least 3 hours before the next meal.

(12) Candy, ice-cream and other sweets should not be eaten between meals, especially just before a meal.

(13) Regularity of meals is important. Have the meals at the same time every day.

(14) Prevent constipation. Coarse breads (graham and whole wheat), fruits, and vegetables will usually take care of this.

(15) Allow enough time for meals so that food may be chewed well. Mealtime should be a resting period for children.

The May issue of the *Southern Medical Journal* is devoted to a Symposium on Malaria. Problems treated are malarial relapses, necessity for malarial statistics in demonstration areas, urban malaria control, rural malaria control with the county as a unit, fish as an anti-mosquito agency, and the use of oil in the prevention of malaria.

The Bureau of Rehabilitation has come in contact with 2,604 industrial cripples, has registered 1,967, has assisted 936, and has terminated 845 cases because the persons no longer needed assistance or because they could not be located.

### The Prophylaxis of Deafness

Parrel (*Jour. des Practiciens*, March 11, 1922) discusses this question which is so important from the social viewpoint. His conclusions are, that it is certain that the auditory troubles of children may be decreased by the regulation of the marriage of syphilitics and by advising against consanguinous unions of the descendants of families in which deafness is common. Naturally, it is necessary to treat syphilitic parents, syphilitic pregnant women, and the issue of syphilitic parents. He recommends the instruction of mothers in the rules of oto-rhino-pharyngeal hygiene and to teach them to accept without hesitation the intervention of a specialist to open up and disinfect the upper air passages. This will diminish very considerably the number of deaf adults. The majority of cases of deafness in adults have their point of departure in the rhino-pharyngeal affections of infancy. These occur as a rule in the nasal fossae, the tonsils and the pharynx. The frequency of otitis media in nurslings should not be forgotten. The medical inspectors of schools and colleges and the physicians of school infirmaries should exercise in collaboration an active surveillance of pupils from the acoustic and respiratory points of view, since in this way many cases of deafness may be discovered in time to permit an efficacious attack upon the causal disease. There should be a greater number of clinics for the periodical examination and treatment of infants and children in order that deafness may be prevented, ameliorated, or cured. The social importance of deafness does not require demonstration, since the inferiority of the deaf person manifests itself under all circumstances. It is the duty of physicians to emphasize to instructors and parents the importance of the prophylaxis of deafness and the ways by which the sense of hearing may be protected. These methods will no doubt reduce very considerably the prevalence of deafness.

The Central University of Mexico, which is entrusted with the revalidation of foreign diplomas, has announced that hereafter in order to prevent abuses by quacks, no foreign diplomas will be recognized. Physicians graduated from foreign countries will have to submit to a new and complete examination in order to have their degrees recognized in Mexico.

# Disinfection After Infectious Diseases

BY D. L. RICHARDSON, M.D., SUPERINTENDENT, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

THE subject of terminal disinfection after infectious diseases is of widespread interest to hospitals and the public. No more frequent question is asked concerning isolation of contagious patients than what to do to the patient and room at the termination of the disease.

This paper will be confined to disinfection after scarlet fever, diphtheria, measles and diseases which we know to be transmitted by contact.

Terminal disinfection after insect-borne diseases, such as typhus fever, yellow fever and malaria, is quite unnecessary except to destroy infected insects. Isolation in such diseases should aim to prevent insects from becoming infected by the patient, and infected insects from biting well persons. Germs of such diseases are carried in the bodies of infected insects and contact with the patient offers no danger unless infected insects are about. Terminal disinfection after these diseases should be confined to measures to kill all insects in the quarters occupied by the patient.

The contact diseases constitute quite another problem. During the course of the illness the virus escapes from the body either in secretions or excretions of the body or in wound discharges. These are likely to be spread about more or less generally unless great care is taken to prevent that practice, so that theoretically any small or considerable portion of the room occupied by a patient or its contents may be contaminated.

From a practical point of view, however, it has been found by experience that the whole room and its contents are not contaminated. The things which are most likely to be a source of danger are those which most probably have been soiled by the secretions or excretions and discharges, such as the pillow, the bed clothing, the nursing utensils, bedside table, the chair or chairs occupied by the patient or nurse, the wash bowl and toilet, toilet articles, door knobs, etc. It also must be realized that different objects are contaminated to varying degrees. Germs die rather promptly after leaving the body and, while the process of contamination goes on during the illness, the virus is also being constantly killed by drying and by sunlight. As convales-

*"Fumigation, as ordinarily applied in terminal disinfection, accomplishes very little and is unnecessary. Too much stress has been placed upon contaminated surroundings and too little upon the patient himself or upon those persons whom he has exposed. In contact diseases the whole room occupied by the patient is not contaminated, and fumigation serves no other purpose than to appease the conscience of hospital authorities, health officers and the public. The chief source of infection in contact diseases is not environment but direct and intimate contact with the fresh secretions or excretions of persons who are suffering from diseases in a frank or unrecognizable form and with carriers."*

cence is established, the number of germs discharged from the body constantly decreases so that at the end of the established period of isolation the patient is quite harmless, except in the case of a small percentage of persons who become temporary or permanent carriers. It usually follows, then, that the infection which reaches various parts of a room early in the disease is quite dead, and that a room occupied throughout the entire course of the disease in most instances is harmless at its termination. On the other hand, if the patient dies or is transferred to another room during the acute process of the disease, the vacated room is a much greater source of danger.

This more rational view of room contamination is gaining rapid headway. In the minds of those who still cling to the idea of aerial transmission of disease, the whole room occupied by a patient is a hotbed of infection. Careful observation in the hospital and home prove this view is not tenable.

Fumigation is no longer thought to be necessary and serves no other purpose than to appease the conscience of hospital authorities, health officers and the public. In March, 1905, Chapin in Providence ceased fumigation after diphtheria unless it was requested by the family. In

his annual report for 1908 he statistically shows that there had been no greater recurrence of the disease in homes after discontinuing disinfection than before. In November, 1908 he ceased fumigation after scarlet fever and subsequent experience confirmed the fact that it was not necessary after this disease. Since that time gaseous disinfection after contact disease has been quite generally abandoned in the United States although it is still practiced in many communities and hospitals.

That gaseous disinfection is at least unnecessary, hospital experience has conclusively shown. Since the opening of the Providence City Hospital in 1910 no fumigation has ever been done. There has been no evidence in a single instance that thorough cleanliness of the room and contents was not entirely sufficient. A detailed study of this may be found in an article published by the writer in 1913-1914 Vol. 1, pp. 70-80 of *The Modern Hospital*. It is obvious from this study that no child who contracted an infectious disease in the hospital did by any stretch of imagination pick up the infection from the room which had been previously occupied by the patient suffering from the same disease. The same procedure has been carried out for the prevention of ambulance infection and there is no evidence that any ambulance has ever been a source of disease.

In terminating isolation it should be emphasized that the patient is a far greater potential danger to others than the room he occupied during his illness. He may be a carrier of diphtheria, typhoid, or scarlet fever, as the case may be. It is a very difficult problem to free him from such infection; certainly it cannot be done by any kind of a bath. The room and its contents however are quite free from infection by the time the patient convalesces in it. If, as has been stated, the patient is sent to the hospital or dies in the acute process of a disease, then the possibility of room infection is of some importance. It is not contended that room infection might not be possible, particularly if contents may be smeared with secretions or excretions, but it is strongly maintained that such a source of infection is very slight and that the importance of terminal dis-

infection has been much exaggerated. If the excretions and secretions of the patient have been promptly disposed of and strict cleanliness observed during the nursing of the patient, room infection is trifling.

Terminal disinfection applies first to the patient, secondly to the room and its contents.

It is very proper for the patient to have a bath on discharge; but any infection carried on the surface of the body is not to be compared to the possibility of germs being carried in the nose and throat or intestinal tract. A bath of soap and water, including a shampoo, is quite sufficient. It is not of sufficient importance to require the use of chemical solutions. In the hospital a patient should receive the terminal bath a day before discharge and be placed in a "clean room" so that he will not be sent out of doors before he has had time to dry satisfactorily. This is particularly important after scarlet fever, for exposure may set up rhinitis and if the patient is still a carrier a discharging nose renders him much more infectious. After the cleansing bath the patient should put on clean clothing and the infected clothing be left in the room.

The treatment of the room after discharge of a patient differs in the home and in the hospital. Terminal disinfection of a room in the hospital will first be described. It is assumed that the room has been occupied by the patient alone. The patient's washable clothing, the bed linen, towels, etc., should be collected into a bundle and sent to the laundry to be washed. Mattresses and pillows should be put out in the sun for at least six hours. If the patient dies in the acute stage of the disease or is transferred from the room while acutely ill, or if the clothing is obviously soiled, it should be sterilized by steam under fifteen pound pressure for thirty minutes. Continued sterilization by steam injures the fabric so that mattresses and pillows soon become very much damaged. It is found that sunning in the open air is under ordinary circumstances quite sufficient. Such textile clothing of the patient as is not washable should be hung out in the sun for at least six hours. Shoes, belts, gloves, rubber goods, money and other valuables may be washed with soap and water and air dried, preferably in the sunlight. Magazines, papers and books, should be destroyed or pinned up in a towel and sterilized by steam. All nursing utensils not

damaged by heat should be boiled for at least ten minutes. Thermometers and other small articles can be submerged in 70 per cent alcohol solution or of phenol 1-60 for half an hour. Toilet articles should be washed with soap and water and air dried. The bed, bedside table, chair, bell cord, lavatory, door knobs, curtain cords and the wall about the lavatory and window should be washed with soap and water.

If the patient sick with an infectious disease is in the same room with other patients, it is very important to ascertain whether the other patients are immune to this disease. All those who are susceptible should be isolated separately during a period equal to the incubation period of that disease. The first patient should be isolated as soon as discovered, preferably in a separate room. After his removal disinfection should be carried out just as described above except washing of the walls. The mattress, pillow, bed linen, nursing utensils may be moved with him to the room where he is isolated if it is in the same ward. It is not necessary to clean the whole room or to subject other patients in the room to the same procedure, but the latter should be watched carefully so that symptoms may be detected at the earliest possible moment.

Terminal disinfection in the home is more perplexing because of the presence of many articles of furniture, draperies, shades, carpets, rugs and the like. Again it should be emphasized that the room as a whole is very slightly infected. It is not necessary to destroy these things nor subject them to a damaging process of sterilization. Neither is it necessary to repaint and paper the room.

Methods of disinfection as described for a room in an institution are applicable in a home, including of course the cleansing bath of the patient. The mattress and pillow, blankets, draperies, rugs, etc., should be put out in the sun for at least six hours. Furniture and woodwork can be washed with soap and water, employing a neutral soap so that the finish will not be damaged. Attention should be paid also to the bathroom and fixtures and especially to utensils used by the patient or his nurse, as already described. Utensils which are boilable should be boiled in a pan before being washed. All the linen in the room should likewise be boiled before washing. After airing for forty-eight hours the room is quite safe for any one to occupy.

It is quite right that terminal disinfection should be carried out faithfully but outside of the bed, bed linen and nursing utensils, possibilities of infection are very slight. These methods of disinfection are really of value, but fumigation as ordinarily applied accomplishes very little and is unnecessary. Too much stress has been put upon contaminated surroundings and too little upon the patient himself of those persons whom he has exposed. The chief source of infection in contact diseases is not environment but direct or intimate contact with the fresh secretions or excretions of persons who are suffering from diseases in a frank or unrecognizable form, and with carriers.

The Wisconsin state board of health has appointed Miss Aimee Zillmer of Milwaukee as assistant in education for lecture work in social hygiene and related subjects. Miss Zillmer's last work was with the White-Williams Foundation at Philadelphia.

A State program for mental hygiene, comprising not only measures for preventing and treating mental diseases, but also a center of information on maintenance of mental health and an agency to re-establish paroled and discharged patients, was outlined by Dr. C. Floyd Haviland of Albany, Chairman of the New York State Hospital Commission before the State Charities Aid Association.

### Honored at St. Louis

# Physical Exercise in Preventive Medicine\*

BY VERNER T. SCOTT, CAPTAIN, MEDICAL CORPS, FLIGHT SURGEON, U. S. ARMY, WASHINGTON, D. C.

COMPETITIVE athletics are sports par excellence for gaining an *esprit de corps* for military stations and colleges and if under daily supervision of an experienced medical officer very little harm will result, but from the standpoint of physical exercise, the very ones who need the exercise most are unable to make the team. One should not engage in competitive athletics for exercise alone. The training is intense; invariably comes the slump after the season is over, and in many cases the men are in as bad if not worse condition than before. Moderate daily physical exercise should be the aim. Moderation in competitive athletics is not possible.

Competitive athletics should be encouraged because they are the expression of a progressive race and foster sportsmanship, a much needed element in any country. An experienced medical officer, however, should be consulted in the choice of the athletes and given authority of daily medical supervision.

Mass athletics, although beneficial individually, will not be a success unless compulsory. It has been my experience, as an athletic officer, that the men in good condition take daily physical exercise on their own initiative, while men in poor physical condition lack the energy to take part unless ordered or urged to do so.

Setting-up exercises are too formal and lack the zest found in games. We have found that the exercises valuable to the aviator will be found in volley ball, tennis, equitation, swimming, or golf. Volley ball is gaining in popularity and has the advantage of being simple and available for any number of men. As an exercise for neuromuscular coordination volley ball is unsurpassed. The command to perform the various movements in the setting-up exercises is called by a leader. All the movements of the setting-up exercises and many more are made by a volley ball player in a close contest. The command for these movements originates in the brain of the player and the decision and performance are carried on with lightning-like rapidity. Tennis is a good form of exercise but requires a great deal of skill and, unless matched evenly, the players lose their enthusiasm.

Swimming and equitation are fine outdoor sports and good exercise. The self-confidence and well being they impart should be a sufficient incentive to their universal practice. Golf offers good, conservative exercise but should be alternated with a game of more active movements such as volley ball, tennis, or swimming. A brisk walk of fifteen or twenty miles daily will do more to promote physical efficiency than one-half day a week of golf.

A good physical condition contributes to mental alertness, good health, and high morale. A poor physical condition is conducive to morbid thoughts, petty ailments, and low morale. Whether a bookkeeper or an aviator, physical fitness will be found a factor both in a man's general efficiency and in the degree of health he enjoys.

## Athletics Aids Morale

Physically a man is either in poor condition, fair condition, good condition, or hard condition. A man in poor condition is easily exhausted by mental or physical exertion, is irritable, exhibits a sallow complexion, dull eyes. He usually complains of constipation and headaches, and sometimes of nervousness and insomnia. A man in fair condition strikes a medium between good and poor. A good condition is evidenced by a good physical bearing, an elastic step, bright eyes, and a healthy complexion. Such a man is not easily fatigued, but is physically fit for the mental and physical conflicts of everyday life. Hard condition is that physical state built up by a rigid system of training. It implies a general fitness for competitive athletics, but overtraining for the ordinary routine of life.

In May, 1921, the majority of the fliers were found to be in poor physical condition. With the consent and encouragement of the commanding officer the hour from 11:00 to 12:30 was set aside for exercise. The exercise selected was volley ball. In one month's time there was noted an increase in physical efficiency and a higher morale. Fewer complaints arose out of petty ailments. The exercise has been continued on its merits by order of the commanding officer.

The table below will show the schedules of rating according to Schneider's index. Only the total scores are given, but they summarize the index as taken once a month from May till February, between the hours of nine and eleven a. m. The men were not told the day they were to be tested nor were their habits controlled after 4:00 p. m. Schneider's grades on reclining pulse, standing pulse, and the increase from reclining to standing, increase after exercise, time of return of pulse to normal, and difference in reclining and standing systolic blood pressure. For use by flight surgeons. I have made the following arbitrary divisions: Very good, 17 to 18; good, 14 to 16; fair, 8 to 13; poor, 7 or less.

The table shows a decided increase in the averages after compulsory exercise. There is no steady increase from month to month, nor was it expected where fatigue effects of cross country flights, loss of sleep and excesses were factors to be considered,<sup>2</sup> but it is significant that in spite of these things, physical exercise kept

\*Reprinted from The Military Surgeon, June, 1922.

THE ability to perceive what constitutes true excellence is most often seen in those whose powers of perception have been whetted by comprehensive training and broad experience. It requires a keen and capacious mind to make the fine distinctions that are always contributive to correct decisions.

The enduring preference of the better minds in medicine and dentistry for Colgate's Ribbon Dental Cream furnishes a wholesome admonition to those who still cling to the notion that one tooth paste is as good as another.

Colgate's Dental Powder holds a high position among those of the dental profession who prefer a dentifrice in powder form. As with Ribbon Dental Cream, it is based on the same fine precipitated chalk and pure soap.

A copy of "A Babe in the House" booklet and a generous supply of samples will be sent to registered nurses postpaid on request.

 the Right Way*

the averages for the unit on a higher plane. Nos. 1 and 2 were not affected by the exercise because of the nature of their work. One is a utility and the other an engineering officer. They work in the open day after day and admit they seldom get less than eight hours' sleep at night. No. 3 progressed until December, and in taking the usual history he complained of a headache and said his bowels had not moved for three days. No. 4 in July gives history of very little exercise due to other duties, complains of a headache and constipation and six hours' sleep. No. 6 in June returned the day before from Boston where he flew thirty-five hours in one week making aerial photographs of the city.

From the table we gain the following:

	Before daily exercise	After daily exercise
Very good 17-18..	1 (10%)	4 (40%)
Good 14-16 .....	1 (10%)	4 (40%)
Fair 8-13 .....	6 (60%)	1 (10%)
Poor 7 or less....	2 (20%)	1 (10%)

It is obvious that an hour spent in physical exercise is worth while and compensates for the time taken up when a group of men who are rated physically as 60 per cent fair and 20 per cent poor can be classed a month later as 80 per cent good and very good.

Although physical exercise is the main factor in physical fitness, it will not alone keep a man in good physical

condition. Other factors to be considered are loss of sleep, constipation, excesses and fatigue effects. One hour a day compulsory mass athletics will serve to keep a group of men in a higher state of physical efficiency, increase the morale, and lower the incidence of petty ailments. Setting-up exercises are dull and in no way can be compared to games as a form of exercise. Everything else being equal, one hour a day of physical exercise with eight hours' sleep and one good bowel movement a day will keep any flier fit for any flying duty he is called upon to perform.<sup>3</sup>

## Sanitary Regulations in Illinois Schools\*

### What Shall It Profit a Child to Gain Knowledge and Lose Health?

BY HARRY F. FERGUSON, CHIEF SANITARY ENGINEER, STATE DEPARTMENT OF HEALTH, SPRINGFIELD, ILL.

UNDOUBTEDLY many of the troubles that affect one in later life have their start at school age, and it is quite probable that some of these troubles are the result of insanitary conditions at our public schools. We require by state law that children attend school. Is it not, therefore, wrong to neglect to furnish them at school with good air, adequate heat and light, good water supply, sanitary toilet facilities, comfortable seats and desks, and general cleanly and sanitary surroundings?

The effect of school attendance on health and growth has been investigated in several countries, and from these investigations it has been determined that elementary schools have had a noticeable effect. Some of these studies and investigations are reported by O. W. Hallin in the *Journal of the American Public Health Association* for September, 1919. A physician at Gottenburg, Sweden, kept weights for twenty years in three girls' schools. He weighed each pupil twice a year, at the beginning and at the end of the three-month vacation period. These records show a monthly gain in weight greater for the three-month vacation period than for the entire nine-month school period. For pupils eight years of age the gain for the three-month period was one-

fourth greater than that for the nine-month school period, and the gain for the three-month period over that for the nine-month period increased as the age increased and was three times for pupils fifteen years of age. An-

other physician at Leipzig states that the height and weight increase for pupils for the first year at school is less than for any other preceding year.

Seeking a probable cause for these

A proper heating system is necessary to the health of the child in the rural school. The illustration shows a room heater jacketed like a furnace. (a) Represents the foul air flue; (b) the chimney tile; (c) the opening into foul air flue, and (d) the door which controls the supply of air to the furnace.

Agencies in 234 other cities

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said. "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank* and *natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

**Cantilever Shoe**

Endorsed by Women's Colleges, Women's Clubs, Public Health Authorities, Physicians, Osteopaths, Directors of Physical Education, Editors, Stage Celebrities and prominent women everywhere.

recorded harmful effects on children of attendance at school it would seem evident that among the factors detrimental to the health and welfare of the school children might be considered (1) deficient sanitation including air, heat, light, water, toilet facilities, and general sanitary conditions, (2) deficient physical exercise, and (3) mental overstrain or fatigue.

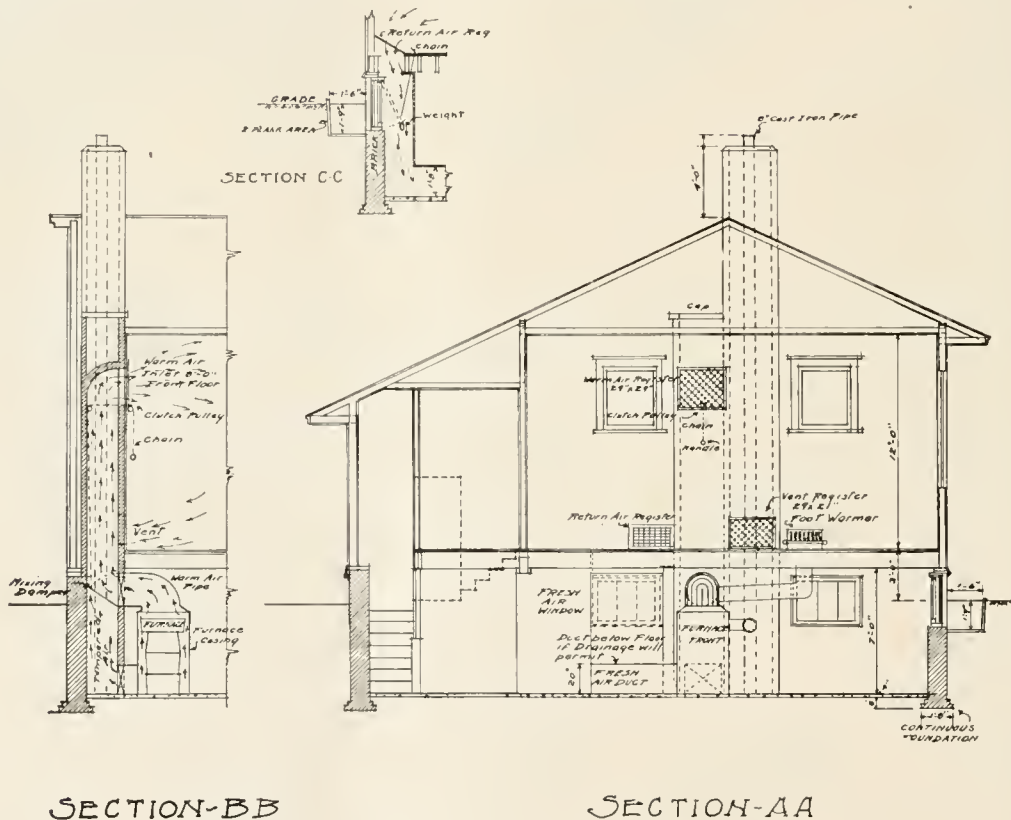

A sanitary school will not only protect the health of the school children but it should serve as a model in sanitation for the guidance of the entire community in which the school is located. A school should be pleasing and attractive in appearance, in furnishings, and in surroundings, so that the

does not specify in detail the conditions that must exist, but authorizes the State Superintendent of Public Instruction to prepare, with the advice of the State Department of Public Health, the State Architect, and the State Fire Marshal, specifications and standards for the guidance of school directors and boards of education. The specifications for minimum requirements cover heating, ventilation, lighting, seating, water supply, toilets, and safety against fire.

The law makes it the duty of the county superintendents of schools to inspect plans and specifications for school buildings that are submitted to them by boards of education or boards

to him to be insanitary or unsafe and upon receipt of an unfavorable report from any one of the above State agencies the county superintendent shall condemn the building and notify in writing the board of directors or board of education. When a board of trustees has had notice from a county superintendent that a district has not kept school as required by law, that part of the State distributive fund apportioned to such district shall be withheld until the county superintendent has given notice in writing that the requirements of the law have been complied with.

For new school buildings there should be no difficulty or excuse for

Cross section of school, showing air currents.

community as a whole may be proud of it and so that pupils will take an interest in the school and will endeavor to carry out at home their knowledge of sanitary conditions gained both from teachings and observations at the school.

Appreciating the injustice of requiring school attendance when school buildings are insanitary and detrimental to the health of the pupils, the legislature in 1915 amended the school law so as to provide that every school must be constructed and furnished so as to protect the health and safety of the pupils and the teachers. This law

of directors, and to approve those plans which comply with the specifications and requirements prepared and published by the State Superintendent of Public Instruction. It is the duty of the county superintendents also to inspect existing public schools under their supervision and to notify the proper school officials whether the schools meet the minimum requirements.

A county superintendent has authority to request the State Department of Public Health, the State Fire Marshal, or the State Architect to inspect school buildings which appear

not fulfilling all sanitary requirements. In planning a new school the first decision that must be made, in which sanitary conditions are involved, is the suitability of a site or sites. Unfortunately sometimes school buildings have been poorly located because of jealousies existing between different factions in school districts. These personal jealousies should be submerged for the best interests of all the school children and thus eventually for the best interests of the community. The site should be considered from the standpoint of general drainage conditions, water-sup-

In the first picture of this series of two the seat is too high and the boy's feet cannot touch the floor; the second shows the correct size of both desk and seat.

ply possibilities, sewage-disposal facilities, objectionable noises such as from industrial establishments, railroad yards, street-car lines, etc., and the site should be such that the air will be clear and clean and that light will not be shut off by other buildings or too many trees. Drainage conditions should be such as to afford good playgrounds as well as to maintain the site of the building dry.

In planning the new building itself the requirements adopted and published by the State Superintendent of Public Instruction should be complied with. For the country and smaller schools and layout and arrangement for "standard schools" prepared by the Superintendent of Public Instruction are valuable guides and for the larger schools the services of an architect experienced in school design and sanitary requirements is essential for working out suitable detail plans.

A considerable number of existing schools were constructed before the full importance of sanitary conditions was appreciated, and it is now necessary to study the existing school buildings to note their defects and insofar as possible to correct any defects by alterations or additions, or, if necessary, build new buildings. Since the passage of the amendments to the school law by the 1915 legislature considerable progress has been made in the improvement of unsatisfactory school buildings. In this work the Division of Engineering and Sanitation of the State Department of Public Health has cooperated and has

made a considerable number of sanitary inspections at the request of the county superintendents of schools, local school officials, and parents of school children. These sanitary inspections cover heating and ventilation, lighting, seating, water supply, toilet facilities, and general sanitary and drainage conditions.

The heating and ventilation in a school building are satisfactory when a proper temperature is constantly maintained, when the humidity is not too low, and when there is a proper change in the air in each room, especially the classrooms. It has been stated that pure air will possibly cure as many ills as medicine and will prevent more ills than it will cure. Bad air makes pupils drowsy and the brain dull and thus not only injures the pupils, but interferes with the aim of the pupils in going to school, which is to gain knowledge.

#### Sanitary Rules for Schools

The temperature of a schoolroom should be about 68 to 70 degrees Fahrenheit, and the humidity should not be too low. If air at 20 degrees is raised to a temperature of 68 degrees without adding moisture, then the resulting air is only about one-seventh saturated. If air at 20 degrees and a humidity of 70 degrees is raised to 68 degrees, then the humidity will be only 12. It is considered that a humidity of at least 50 is desirable except near cold windows and in extremely cold weather, when a humidity of 40 might be permissible.

In school buildings of more than

one room having heating equipment in the basement the problem is to distribute the heat properly to the different rooms and to remove the foul air through suitable vent openings connected to foul-air flues. Information on installations for hot-air furnaces and steam and hot-water heaters is given in a circular published by the State Department of Public Instruction dealing with standard elementary schools. With a central heating plant positive ventilating systems which require the use of a fan or blower or the gravity of so-called "direct-indirect" systems which rely upon a natural movement of air caused by difference in temperature can be used.

For the smaller school buildings without a basement the problem is the installation of a heater in each room, which will not only heat the room and afford suitable ventilation but will not subject the pupils near the stove to too warm temperatures. A room heater should be installed with a suitable jacket so that it will form virtually a warm-air furnace.

It should be installed so as to bring in air from outdoors and from the floor near the entrance doors and heat the air as it passes by the furnace. The size of grate areas, fresh-air ducts, and smoke and ventilating flues for rooms of different capacities are given in the circular published by the State Superintendent of Public Instruction.

With proper heating and ventilating systems, fresh air from the outside will be brought into the school building and warmed to a proper temperature. The warmed air rises to the top of the rooms and the foul air being colder sinks to the floor and ventilating flues remove it from the rooms. Thus a constant supply of fresh air and removal of foul air results. With the gravity system of ventilation the circulation of air will decrease as the temperature of the outside air increases, but with the warmer outside temperatures additional ventilation can be gained by means of windows.

The detrimental effects of inadequate or wrong lighting upon children, who naturally have perfect vision, are slow to be noticed, but when they do become noticeable it is often too late to correct the impaired vision. Moreover, during the time the pupil has been subject to unnecessary eyestrain the quality of his work has undoubtedly been below what it would have been if adequate lighting facilities had prevailed. The affects of

# When appetite must be increased without the aid of exercise

**I**NVALIDS are often unable to stimulate their metabolism with exercise, yet appetite must be increased, more food ingested and the plane of metabolism raised.

Many foods fail in such a situation because the vitamin they contain is associated with substances rich in calories.

"In such cases" says one of America's foremost physiological chemists, "Yeast appears to offer the best means for furnishing a relatively large quantity of the water-soluble vitamin together with a comparatively small proportion of calories."

**T**HE importance of good appetite is brought out in one of the leading works on deficiency disease. Loss of appetite, says the author, interferes with the liberal consumption of food which is the first necessary step in maintaining health, and the depressed function of the gastro-intestinal tract interferes with prompt digestion and absorption and also with the prompt evacuation of undigested residue from the intestines which is an absolute essential of health and vigor.

Fleischmann's Yeast is a pure food, proved by strictly scientific tests to be potent in increasing appetite and raising the plane of metabolism.

poor lighting upon the eyes of school children may be comparable in a way to the eventual wearing of a stone by the constant action of drops of water. The effect of a few drops is not noticeable, but repeatedly subjected to dropping water, the stone will wear.

The requirements for lighting adopted by the State Superintendent of Public Instruction are as follows:

There shall be no windows in the wall which the seated school children face. The walls shall be a soft light tint, gray, tan, or very light olive green. The ceiling shall be a very light tint.

In school buildings hereafter erected or remodeled the windows shall be at the left of the seated pupils. Windows at the back of the room are permissible, but shall be at least six feet from the floor.

The windows at the left shall be set with the least possible space between them and shall be not less than 3 feet nor more than 4 feet from the floor.

The glass surface in study rooms shall not be less than one-fifth of the floor space. When the light is from the north only or when trees are near-by, it shall be not less than one-fourth of the floor surface.

All windows shall be provided with good adjustable shades.

In all buildings windows in the wall which the seated pupils face shall be permanently walled up, so that no light may enter from that direction.

If there are full length windows on the right toward the front of the seated children, the lower sash shall be covered so as to shut out the light from that part completely. If this makes the light insufficient, additional windows shall be provided at the left.

Windows in front of the pupils are especially bad because the light shines directly into the eyes and either causes eyestrain or requires the pupils to bend their heads down into unnatural positions or hold books high so as to shut off the light reaching the eyes from in front. The windows on the left of pupils should be spaced as closely together as possible in order to provide even lighting in the room and prevent cross lighting.

Proper seating facilities can not strictly come under the classification of sanitary conditions but seating facilities are noted by sanitary engineers of the department in making inspections of schools inasmuch as the arrangement of seats has to be considered in connection with lighting conditions. The requirements for Illinois standard schools provide that each schoolroom shall be furnished with single desks which are of proper sizes and adjusted for the pupils who occupy them. The circular published by the State Superintendent of Public Instruction gives the sizes of desks necessary for pupils of different ages

Improper seating has a direct effect on the health of the child, especially in connection with lighting conditions and as such gains the attention of the sanitary engineer in inspection. The first of the series of three pictures shows the desk too high; the second the desk is lowered but the seat is too far away from the desk; in the third the seat does not strike the shoulders of the boy.

and information as to their proper location.

### Inspected Water Supply

If a public water supply of good sanitary quality is available then only that supply should be furnished at the school building and grounds. If a safe public water supply is not available, or if there is no public water supply, then a private supply must, of course, be developed from wells or cisterns or in some cases from springs. Whatever the source of supply it should be certain that it is not subject to contamination. If a well is used as a source of supply, it should be so constructed and located that the water will not be subject to contamination either by underground seepage or at the top by surface water and waste pumpage. Drilled or driven wells cased with iron pipes are preferable, but wherever soil formations do not permit the installation of drilled or driven wells, dug wells can be made satisfactory if the walls are properly constructed and the tops suitably covered. The walls should be made water-tight for a distance of 8 to 10 feet below the surface of the ground and the tops should be covered by means of substantial sloping concrete platforms and drains for excess pumpage provided. Manhole openings can be provided in the tops of wells to afford access for inspection and cleaning, but these openings should be protected by suitable covers so that the entire top will be water-tight. Bulletins describing the upper construction of wells will be sent by the State Department of Public Health on request.

The distance that a well must be from a cesspool, privy, or other source of pollution, that might contaminate the well by underground seepage, depends upon the type of well installed and the character of the underground

formation. If the well is of the drilled or driven type and passes through an impervious layer of hardpan or compact clay, then it could be located nearer sources of pollution with less danger of contamination than if a dug well were installed. It may be stated that on an average a dug well should be at least 100 feet from any source of contamination. If a satisfactory well supply can not be obtained, cisterns can be used. Cisterns should be water-tight to prevent infiltration of shallow ground water. They should preferably be provided with effective filters which should be cleansed once a year.

If a spring is used all possible information as to the source of the spring water should be obtained. It should be assured that the spring water is not subject to pollution underground or at the spring itself. It is a faulty and somewhat common belief that all spring water is safe, when actually springs are subject to as much if not more contamination than wells in similar surroundings.

Analyses of samples of water are made free by the State Department of Public Health. Analyses are made only of samples collected in suitable containers which are sent by the department on request. In case the analyses show an unsatisfactory water and the reason for the unsatisfactory results are not apparent from the information given by the person submitting the sample, an inspection by a sanitary engineer of the department can be made. If a school district is planning to develop a new source of water supply for a school the opinion of the State Department of Public Health upon the proposed new source of supply can be obtained upon request.

The requirements of the State Superintendent of Public Instruction include the following provisions rela-

# Essential Points

*in the*

# Diet of Growth

1. The food must contain those food accessory substances known as vitamins, but the presence of the vitamins is not sufficient in itself.
2. The food must be well balanced, for a deficiency in one element means the ineffective action of the other food elements.
3. The vitamin-containing food even though well balanced must be one that is easily assimilated. It is a physiological crime to clog the system with fats that cannot be digested.

**VIROL** as it reaches the public contains the vitamins; it is well balanced, and can be assimilated in the most delicate conditions. That is why **VIROL** is used in more than 2,500 hospitals and infant clinics.

*The presence of vitamins in VIROL as sold to the public is established by an independent report by the Bio-Chemical Department of the University of Cambridge, a copy of which will be sent to any member of the medical profession on request.*

# VIROL

*Sole Agents for United States*

Geo. C. Cook & Co., Inc., 59 Bank Street, New York

tive to the distribution of water within the school: (1) *Water Containers*. Where drinking water is kept in the schoolroom it shall be kept in a clean container, provided with a cover and a faucet. (2) *Individual Cups*. The use of the common drinking cup is prohibited by law. When cups are necessary each person shall be provided with his own cup. These shall be placed in a dustproof case, which shall be kept closed except when removing or replacing a cup. The cups shall be kept clean. (3) *Bubbling Fountains*. Bubbling drinking fountains are strongly recommended. No fountain shall be installed which enables the lips to touch the opening of the water pipe.

### Toilet Facilities

The problem of toilet facilities and disposal of sewage from school buildings may be divided into four general classes: (1) Where a public sanitary sewer system is available; (2) where a public sanitary sewer system is not available but running water is available and a private sewage-disposal system can be installed; (3) where chemical toilets are feasible; and (4) where ordinary privies are to be used.

If a public sanitary sewer system is available then the question of toilet facilities is easily solved by the installation of standard plumbing fixtures and connection of a school sanitary drain to the sanitary sewer system. If a public sanitary sewer system is

not available but running water is available and plumbing fixtures are to be installed in the school building, then it becomes a problem as to how to dispose of the sewage. Generally this can be done by installing a suitable sewage settling tank and discharging the overflow from the tank into an outlet tile to a watercourse or to a surface disposal system. Fortunately schools are not in session during the summer months when the flow in streams is the lowest, and thus the possibility of objectionable stream pollution by discharge of partially treated sewage is minimized. In installing a sewage tank it should be realized that a tank does not thoroughly purify sewage but simply serves to remove a portion of the suspended solids and a portion of the organic matters. Each installation must take into consideration local conditions, such as proximity of wells to the school sewer and tank; the location, character and use of the outlet watercourse; and the possible location for a sewage tank. When a school district is planning to install such a system the advice of the State Department of Public Health should be obtained.

Chemical toilets, when properly installed and properly maintained, are an improvement over the ordinary privy. There are several suitable installations on the market and school-district officials should have no difficulty in securing satisfactory installations. Installations of privies

should be made so that they will be fly-tight and will not serve as a source pollution to any wells in the neighborhood. Bulletins dealing with sanitary privies may be obtained from the State Department of Public Health. The requirements of the State Superintendent of Public Instruction included the following provisions relative to outdoor toilets:

The boys' toilet shall have a tight board screen at the front and side not less than 5 feet high. Behind this shall be substantial zinc-lined urinal troughs. The lower one shall be 16 inches from the ground and the higher one 26 inches from the ground at the highest point. When dry closets are used the urinals shall drain into a separate underground receptacle.

The toilet buildings shall rest on a substantial brick or concrete foundation to which they shall be securely bolted. The buildings shall be well-lighted and shall constitute an adequate protection against inclement weather. There shall be at least two seats and not fewer than one seat for every 20 children using them. One or more seats shall be 10 inches high, the rest 16 inches.

Where there is danger of contaminating the well, the vault shall be concrete, so constructed as to prevent leakage of sewage and so that it may be cleaned. Light shall be completely shut out of the vault. The seats shall be provided with covers, securely hinged in such a way as to close automatically. The vault shall be ventilated with a flue, and a cross-sectional area of not less than 64 square inches and extending from the vault through the roof. One of the chief aims is to shut out flies, which spread contagious diseases.

## Food Conditions in the Cook County Jail\*

ANYTHING approaching an adequate survey of the food situation in the County Jail could be made only after a first hand study,—living at the jail and following through the whole course of successive days. This has not been possible. With the cooperation of Captain Westbrook, the warden, and his assistant, the Committee of Dietitians visited the kitchen several times, inspected the raw food materials, examined the prepared foods, watched the serving, and noted in a general

way the amount of waste. The report is destined to present merely a general picture of conditions as noted by a committee accustomed to supervising the cooking and serving for large groups.

It is evidently the intention of the County to furnish the persons held in the County Jail an inexpensive diet that is adequate to maintain them in proper physical condition. A more detailed study made by Winthrop D. Lane reports on the kind and character of the foods served. The present food served, though sufficient in quantity and for the most part wholesome in quality, does not constitute a balanced ration. It lacks fat, no fat being served except that contained in the meat. It lacks sugar,—no sugar being included in the general diet. The amounts of fat and sugar incorporation in the broad are-

negligible. It lacks food that contains vitamins, a factor of increased importance because of the fact that nearly twenty per cent of the inmates are boys,—2,000 out of a total of 8,600 in 1921. The previous food habits of the inmates should not be the criterion, as those very habits may have been a contributory factor in their delinquency. The foods are not well distributed. Rice, potatoes, and bread are served at one meal with no other vegetable; or potatoes, hominy and bread at another.

With a budget of thirty-six thousand dollars and a census of approximately 850, the menu must of necessity be limited. No doubt habit and precedent play an important part both in the buying and ordering, as well as the preparation of the food. It takes imagination and much planning to vary a twelve cent or less

\*Section of a report on a survey of conditions at the Cook County jail, made under the direction of the Chicago Community Trust. The recommendations in regard to the dietary published herewith are the result of a study undertaken by a special committee of the Chicago Dietetic Association consisting of four members, as follows: Emma B. Aylward, dietitian, Presbyterian School for Nurses, chairman; Elizabeth Tuft, dietitian, Wesley Memorial Hospital; Breta Luther, dietitian, Cook County Hospital, and Rose Straka, dietitian, Presbyterian Hospital.

# KOTEX

## —Sanitary Pads Made of Cellucotton

From scientific selection of material to finished product, Kotex is designed for one purpose—a sanitary pad more highly efficient than any yet devised. A sanitary pad easy to dispose of and cheap enough to throw away. Kotex are a revelation of comfort and convenience to women.

Physicians and nurses recommend Kotex because of their extraordinary absorbent qualities which, in the form of Cellucotton, first

won the attention of army surgeons in France, and was there adapted by war nurses to their own needs.

Kotex come in two sizes—Regular and Hospital. The Regular size Kotex has a Cellucotton filler 9 inches long by 3½ inches wide, in gauze 22 inches long—generous ends for pinning. The Hospital size is longer with additional thickness, and therefore even greater "absorbency." Kotex are sold in drug, dry-goods and department stores everywhere.

**INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX**

per capita menu to any considerable degree. A few suggestions are, therefore, included in this report in the form of a week's menus worked out on the present day capita cost. The prices taken are from invoices of materials received in May of this year, and prices given Mr. Henry A. Zender, the County Superintendent of Public Service, and by firms furnishing foodstuffs to the jail. Requisitions for twenty-eight days in the month of April are as follows:

**Classification Supplies**

<b>Meat—</b>	
Salt Pork .....	6 pounds
Chuck .....	6,380 pounds
Corn Beef .....	1,900 pounds
<b>Fish .....</b>	
Lard .....	60 pounds
Milk .....	299 gallons
Flour .....	147 sacks
Macaroni .....	2 barrels
Rice .....	300 pounds
Peas .....	1,900 pounds
Beans .....	900 pounds
Potatoes .....	135 sacks
Cabbage .....	40 sacks
Carrots .....	18 sacks
Turnips .....	33 sacks
Onions .....	2 sacks
Tomatoes .....	9 cans
Sugar for women .....	174 pounds
Syrup for women .....	42 cans
Jelly for women .....	120 cans
Coffee .....	1,300 pounds
Tea .....	10 pounds
Salt .....	3 barrels
Pepper .....	12 packages

The Comptroller's report for 1921 shows that of the \$34,537.53 spent for food, the \$15,403.22 was spent for meat. The inclusion of some butter or butter substitute, and milk in place of the meat would undoubtedly have saved much waste of bread and cereal and would have resulted in a better balance. The total of 147 sacks or 105 barrels of flour is an average of three and one-half barrels per day, enough to make 850 to 900 pounds of bread, or one pound per person per day, three-fourths pound is sufficient with other starchy foods in diet. Split pea soup is served three times per week.† The monotony of having the same soup repeated every second day is a guarantee that much goes down the sewer.

One thousand three hundred pounds of coffee, serving every morning and alternate evening, eighty and ninety gallons, allows thirty pounds per meal, a sufficient amount. If the coffee were ground finer and a muslin bag used instead of the burlap sack now in use, the results would be more palatable. Scalding the milk would improve the flavor and lessen the possibility of serving cold coffee, which seems to be a general complaint.

†Note the requisition for 1,900 pounds of split peas!

It is deplorable that the serving of the food should of necessity be so primitive. Whether the primitive way the men act is a reaction to existing conditions or natural to this group, was not a matter for the consideration of the Committee, but it is to be hoped that in the new jail some more civilized and civilizing method of serving will be instituted.

The jail diet is based upon a budget of thirty-five thousand dollars per year, or approximately ninety-five dollars per day for 850 to 900 people, representing about eleven cents per day per capita. The typical meals for a day are as follow:

**Breakfast.**—Clear coffee and duffer (bread).

**Dinner.**—Beef stew, potatoes, a vegetable (carrots, turnips, or cabbage), and bread.

**Supper.**—Coffee and duffer, or soup and duffer.

Total food allowance for day	Carbohydrates	Protein	Fat
Bread, 1 lb. ....	254	43.2	9.6
Meat, ½ lb. ....	..	48	31.2
Potato, ½ lb. ....	32	3.2	..
Carrot or Cabbage or Turnip, ¼ lb. ....	7.2	1.2	..
Dry Peas, 1½ oz. ....	24.8	9.6	.4
Coffee .....	..	..	..

Total grams ..... 317.0    105.2    41.2  
 Total calories ..... 2,048  
 Theoretically, the carbohydrate and proteid are high for people not working. Fat low. In practice this amount of food is not eaten and is therefore insufficient.

A reasonable proportion of carbohydrate, proteid and fat for average person living in confinement, is approximately:

Carbohydrates	Proteid	Fat	Calories
250 grams	75 grams	100 grams	2,200 to 2,600
Breakfast—Typical	.....	.....	\$27.90
<b>Dinner:</b>			
Hamburger—225 lbs. @ 10c. ....	.....	.....	\$22.50
with Onions—25 lbs. @ 2c. ....	.....	.....	.50
Potatoes—300 lbs. @ \$2 cwt. ....	.....	.....	6.00
Bread—225 lbs. ....	.....	.....	7.00

<b>Supper:</b>			
Stewed fruit .....	.....	.....	\$ 9.00
Bread—250 lbs. ....	.....	.....	7.00
Coffee, with milk and sugar. ....	.....	.....	7.50
Margarine—25 lbs. ....	.....	.....	5.00
.....	.....	.....	28.50
.....	.....	.....	\$92.40

Breakfast—Typical .....	\$27.50
<b>Dinner:</b>	
Salt Cod Fish—75 lbs. @ 10c. ....	\$ 7.50
Milk gravy—	.....
40 gal. milk @ 18c. ....	7.20
5 lbs. oleomargarine @ 20c. ....	1.00
15 lbs. flour @ 3c. ....	.45
Potatoes—450 lbs. ....	9.00
Bread—225 lbs. ....	7.00
.....	32.35

<b>Supper:</b>	
Vegetable soup, made from stock from bones—	.....
Cabbage—25 lbs. ....	\$ 0.75
Carrots—25 lbs. ....	.50
Onions—10 lbs. ....	.20
Barley—20 lbs. ....	.60
Flour—10 lbs. ....	.30
Bread—225 lbs. ....	7.00
Stewed fruit .....	9.00
.....	18.35
.....	\$77.20

**Suggested Meal Changes**

**Breakfast.**—Cereals—Oatmeal, oatmeal, and bran, cornmeal, rice.

**Dinner.**—Fish with macaroni and tomatoes—no potatoes. Bread. Serve vegetable soup for supper. Hash with beets or raw onions when cheap. Bread. Stew with turnips or carrots and potatoes. Bread. Cornbeef and cabbage with potatoes and bread. Baked beans with ham butts. Potato and sausage loaf; 2 parts raw potatoes, 1 part sausage and gravy.

**Supper.**—Stewed fruit, prunes, apricots, peaches, dried apple sauce. Vegetable soup. Potato soup with salt pork; bean or pea soup, with bacon ends or salt pork. Bread.

All of the above changes on a per capita basis not exceeding the present cost.

For a fifteen cent per capita add to the above: A meat substitute for supper, i.e., rice and tomatoes and cheese. Potatoes with bacon.

Fresh fruit for breakfast, occasionally. More milk, and more fat.

For a 20 cent per capita: Add milk, eggs, fat and sugar in the form of simple puddings.

**THE WAGES OF GOLF IS HEALTH.**

**Suggested Meals**

BREAKFAST		Carbo-hydrates	Proteid	Fats	Total Calories

*In one small unit—*  
**Complete Sterilization**

**I** NSTRUMENT and Dressing Sterilizers are combined with Water Sterilizer in one compact service-giving outfit. It is a new unit, but has years of practical experience behind it. The money cost to you is exceedingly moderate.

It is the Castle No. 1512. Dressings are sterilized by "live" steam, instruments by boiling. The table top is heat and acid proof, and beneath is an aseptic cabinet for supplies. Illustration shows gas heat, but made also for other heats. Electric unit never can boil dry.

*CUT out this Castle ad. and send it to your dealer for further information. Or ask us directly any question you think of concerning your own particular sterilizing problem.*

**WILMOT CASTLE CO.**  
 1153 UNIVERSITY AVE., ROCHESTER, N. Y.

*Makers also of complete group of Pressure Sterilizers for Hospitals and Laboratories.*

**LOESER'S INTRAVENOUS SOLUTIONS**

CONTROLLED BY  
 CHEMICAL, PHYSICAL AND BIOLOGIC TESTS  
 Loeser's Intravenous Solution of  
**IRON and ARSENIC**

A sterile, stable solution in hermetically sealed nonsoluble glass ampoules. Each ampoule contains 64 milligrams (1 grain) of Iron Cacodylate.

Permits the Intravenous Injection of a Hemotonic of Established Therapeutic Value.

The Intravenous Injection overcomes every question of absorption and warrants the expectation of improved clinical results as compared with other methods of administration.

READY—July Journal of Intravenous Therapy. Special Anemia Number.

Abstracts and references from American and foreign Journals.

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions for the Medical Profession Exclusively.*

### Virginia Child Labor Law

A new child labor law was passed by the Virginia legislature, the provisions of which apply to work in, about, or in connection with any gainful occupation except work on farms and in orchards and gardens. The minimum age is fourteen; the maximum hours are eight per day, forty-four per week and six days per week; work between 6 p.m. and 7 a.m. is prohibited; employment certificates, issued by local school officials, instead of by any notary public as heretofore, are required for employment of children between fourteen and sixteen. The requirements for the issuance of these certificates are: (1) a promise of employment; (2) proof of age; (3) a certificate of physical fitness signed by a public-health or school physician.

### The Drug Menace and Its Serpentine Trail

Trade methods of scientific salesmanship mark the practices of illicit opium sellers who give out "samples" to youngsters at school. They soon become regular customers, according to Sara Graham Mulhall in *Current Opinion*. Recruits are thus secured to the great army of regular buyers of habit-forming drugs. The Opium Ring's minions serve perhaps two million users, and the number is increasing so rapidly and by such insidious means that there is no way to get an authoritative, up-to-the-minute census.

Imported for legitimate use in the United States, in 1909, was 470,000 pounds; in 1919 the amount had increased to 730,000 pounds, enough to supply thirty-six doses to every man, woman, and child in the Nation. If the increase was proportional in 1920 and 1921, the opium imported into this country is appalling, enough to poison the brains and corrupt the morals of the Nation, for 90 per cent of the opium imported into this country is used by addicts.

As shown by the latest available figures the United States is the greatest opium importing and exporting nation in the world: Austria imports 4,000 pounds; Italy, 6,000; Germany, 17,000; Portugal, 2,000; France, 17,000; Holland, 3,000; as against 470,000 pounds for America! New York leads with its thirty-five thousand recorded narcotic addicts. Tennessee follows next, then Missouri, Virginia, Michigan, Illinois, Georgia, Oklahoma, Massachusetts, and so on in order of drug addicts reported, irrespective of population.

A survey of the Nation shows that most of the addicts to heroin are girls and boys under the age of twenty. The cocaine habit is also fastened upon youth to a greater extent than upon adults. Careful government inspection has shown that the greater part of the drug victims are women and girls, though in some sections the proportion is about equal for the sexes.

Economically, the country loses some two hundred million dollars a year in service from the men and wo-

men incapacitated by the drug habit, while the addicts themselves pay approximately one hundred million dollars a year for their "dope," not to mention the billion dollars spent for cure and upkeep of those deplorable citizens who become a public charge upon the tax payer.

The drug addict is a national menace. The Nation should control its source of supply, put its heel on the illicit trafficker, and check this undermining curse, says Miss Mulhall.

## Education and the Films

THAT the motion picture is a distinct contribution to visual instruction is the statement of Will H. Hays, President of the Motion Picture Producers and Distributors of America. In 1920 a number of tests were made to prove the efficacy of the motion picture as an aid to acquiring knowledge. Some of these were conducted by Professor J. W. Sheppard of the University of Oklahoma in one of the high schools of Madison, Wis. Abstract and concrete subjects were taught to one group of students by means of film only, to a second group by a superior instructor, and to a third group by an average instructor. The film scored an average of 74.5 per cent, the superior teacher an average of 66.9 per cent and the average teacher 61.3 per cent. In other words, the film outstripped the best teacher by 6.6 per cent and the average by 12.14 per cent.

"A cablegram from Paris a short time ago told how a class of medical students at the Sorbonne University saw by motion pictures the complete details of a wonderful operation performed by the famous surgeon, Professor Jean Louis Faure. The film

was run at a speed synchronizing exactly with the actual progress of the operation and as the details appeared upon the screen another surgeon described every movement made, from the first incision to the closing of the wound by the last stitch. In no way could so great a number of students have watched the life-saving workmanship of a master of his profession.

"In my opinion there will be a series of motion pictures adopted soon by boards of education just as now series of textbooks are adopted. They must be, of course, scientifically, psychologically and pedagogically sound."

A machine which will greatly facilitate the work of visual education in schools and in the home is a new flat disc motion picture projector recently perfected. The machine weighs less than eleven pounds, its disc being only 10½ inches in diameter. Each disc contains 1,300 pictures and is equivalent to 100 feet of ordinary standard motion picture film. By turning the projector in a vertical position pictures can be thrown on the ceiling, thus making the machine valuable to hospitals as well as to schools and homes.

New flat disc motion picture machine which will take motion pictures into the home, school and hospital. Electric batteries in its base supply current, if not available elsewhere, or the pictures can be viewed by daylight projection through the lens of the machine.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

## FROM THE FIELD

The American Occupational Therapy Association will hold its annual meeting at Atlantic City September 25 to 29 inclusive. Among the speakers will be Dr. Frederic Brush, Miss Susan Drew, Miss Winifred Brainerd, Presbyterian Hospital, Chicago, and Dr. H. W. Pollock. Round tables on crafts best suited for mental and nervous cases, for the tuberculous, for bed cases, and for the physically disabled will be conducted during the last session.

The American Chemical Society held its annual fall meeting September 4 to 9 at the Carnegie Institute of Technology, Pittsburgh. Thomas Midgley Jr. of the General Motors Research Corporation will deliver one of the important addresses on "Chemical Control of Gaseous Detonation with Particular Reference to the Internal Combustion Engine."

The American Hospital Association will hold its twenty-fourth annual conference in Atlantic City, September 25 to 28.

A course in the education of the blind will be conducted by the Graduate School of Education, Harvard University, in cooperation with the Massachusetts Department of Education and the Perkins Institution for the Blind. The first meeting will be held Friday, October 6, and on subsequent Fridays till January 26. Edward E. Allen, director of the Perkins Institution, will conduct the course. Charles B. Hayes, director of the division of the blind of the state department of education will assist. The course is designed to give in a short period a comprehensive survey of work with the blind and semi-sighted.

The Second Western Summer School of Community Leadership will be conducted at Leland Stanford, Jr., University, Palo Alto, Cal., September 18 to 23 with the joint cooperation of Stanford University, the League of California Municipalities, the California Association of Commercial Secretaries, and the American City Bureau. Dr. Ray Lyman Wilbur, president of the University, will deliver the lectures on public health.

Miss Bertha Steeves and Miss Stella Fuller are the first Delano Red Cross nurses to be appointed, the former to serve on the islands off the coast of Maine and the latter in Alaska. The Delano Red Cross nurses are supported by the bequest of Miss Delano who died at Savenay, France, in 1919 while National Director of the American Red Cross Nursing Service. The trust fund is to be supplemented by proceeds arising from the sale of her textbook "Home Hygiene and Care of the Sick." A term of acceptance of the appointment is agreement to serve three years. Miss Fuller has been until recently assistant director of the Red Cross Nursing Service in the Southern Division, Atlanta, Ga. Miss Steeves has been an instructor in hygiene in the University of California and has had experience at Henry Street settlement, New York, and in Pasadena, Cal.

The American Dietetic Association will hold its Fifth Annual Meeting in Washington, D. C., October 16-18 with headquarters at the New Willard Hotel. Among the speakers will be Dr. J. P. Watson, psychologist; Dr. Elliot P. Joslin of Boston; Miss Emma Gunther of Teachers' College, Columbia University; and Mrs. Mary D. Bryan, president of the Association. Trips to Walter Reed Hospital and the scientific laboratories of the Government will give excellent opportunities to observe research work being carried on in Washington.

The Annual Roll Call for registration of the Red Cross membership for 1923, will be held from Armistice Day, November 11, to Thanksgiving, November 30. Between those dates approximately 3,300 active chapters at home and abroad will carry on a systematic canvas for support of the peace time work of the nation's officially designated volunteer relief society during the ensuing year. Annual membership will remain \$1. The American Red Cross now has a membership of approximately 4,500,000 adults. An innovation this year will be the uniform card-indexing of the millions of Red Cross members. The stub of each card, of a size handy for card case or pocket book, will be given to each new member enrolling. This

will serve as a certificate of membership.

An industrial conference similar to the Safety Congress formerly held by the New York department of industry will be held in Buffalo, N. Y., November 22 and 23. Elimination of waste in industry will be the main theme. It is hoped that Governor Miller and Herbert C. Hoover, Secretary of Commerce, will open the conference.

The Pennsylvania Department of Labor and Industry has issued in pamphlet form safety standards of the industrial board for laundries. Safety stopping devices for machinery, adequate ventilation and floor drainage, and ample facilities for the personal protection of the handlers of soiled clothing are prescribed.

Arrangements have been made for a free course in laboratory technic for nurses who are graduates of recognized hospitals in the conjoint pathologic laboratories of Boston University and the Massachusetts Homeopathic Hospital. The course covers one year of actual time. Didactic and laboratory instruction similar to that given to medical students is provided in bacteriology and immunology, including Wassermann tests, hematology, urinary analysis, and preparation of tissues. An optional three months course in roentgenology can be arranged in addition, also free of charge.

After eight years of service with the National Tuberculosis Association, Dr. Charles J. Hatfield has resigned as managing director, resignation to take effect October 1, 1922, when he will be succeeded by Dr. Linsly R. Williams who is at present Director of the Commission for the Prevention of Tuberculosis in France of the Rockefeller Foundation.

Alfred D. Flinn, Secretary of the Engineering Foundation, is now on a tour of the west to interest engineers in a wide plan of industrial research, in which the Engineering Foundation, the National Research Council and the government department and the industries will link their efforts.

Framingham Monograph No. 9 deals with influenza, epidemic and post-epidemic observations. It is issued by the Framingham Community Health and Tuberculosis Demonstration of the National Tuberculosis Association.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

The state offices under provisions of the Sheppard-Towner act have been established in the State Board of Health Building at Jacksonville, under Dr. William B. Keating, director of the State Child Welfare Bureau. Approximately \$16,000 will be expended on the work during the next year. The state will be divided into subdistricts with a supervising nurse at the Jacksonville headquarters.

Kansas leads all the states in the union in longevity according to statistics from the Department of Commerce, the average length of life there being 60 years. Wisconsin ranks second in longevity, while Washington, D. C., with an average length of life of 53.83 for white males and 59.83 for white females leads the fourteen cities covered.

The Texas State Board of Health at Austin has for distribution motion picture films dealing with public health nursing, care of the teeth, bacteria, smallpox, diphtheria, the fly, milk pasteurization, the rat, typhoid, and the venereal diseases.

At a special meeting of the house of delegates of the New Hampshire State Medical Society in Concord June 29, it was voted to sponsor a movement for the organization in the state of a public health association composed of professional men and women and interested people for the purpose of promoting public health matters in New Hampshire. The new organization will work in full cooperation with the state board of health.

Detroit Health Department nurses, 133 in number gave 2,838 lectures to school children, explaining the principles of personal hygiene to 117,599 children; they gave 589 lectures to 8,479 mothers on prenatal care and baby health; they made over 200,000 visits to the home; they inspected 4,718 school rooms and examined 197,857 school children; they assisted physicians in 37,938 vaccinations.

Most of the 50,000 deaths in the Philippine Islands in the 1918-1919 epidemic occurred among unvaccinated children according to a report by Victor G. Heiser and Charles N. Leach in the *Journal* of the American Medical Association. Effective vaccination has been exceedingly lax in the Islands since 1909 and the deaths occurred largely among the unvaccinated natives.

The Eye Sight Conservation Council of America, Times Building, New York, is establishing a special mailing list of those who wish to receive material of service to lecturers and writers on the subject of conservation of vision. The Council is stressing the need of lectures before various clubs.

A contest designed to disclose the healthiest negro babies in Detroit was held Tuesday, August 1, in conjunction with the Detroit Urban League at their headquarters, 553 East Columbia Street. Babies were judged in three classes, those up to 6 months inclusive, from 7 to 12 months inclusive, and from 13 to 24 months inclusive.

The application of modern business principles to welfare agencies, and the increased returns on the funds contributed effected thereby, are described in a report made public by the U. S. Department of Labor through the Children's Bureau. This report, entitled "Office Administration for Organizations Supervising the Health of Mothers, Infants, and Children of Preschool Age," is the outgrowth of requests for advice which came to the Children's Bureau from organizations in various cities. It embodies the experience of members of the staff whose services were loaned for studies and consultations, and the results of a study of methods used by 200 nursing agencies in both large and small communities. Although the report is directed especially toward the needs of agencies supervising the health of mothers and young children, certain fundamental principles set forth are applicable to the conduct of any office in the social field.

"Child Health in Erie County, New York" consists of a report of a brief cooperative inquiry into conditions relating to child health and the agencies for dealing with them in the rural sections and villages of Erie County, N. Y., November-December, 1921. The study was made by representatives of the organizations which constitute the membership of the National Child Health Council. According to the introduction, the statements of fact and the recommendations are presented not as a report of a comprehensive survey but merely as a primary contribution toward the coordination of health work for children. They deal with conditions as found in Erie County and are not necessarily considered applicable elsewhere.

Beginning in May, 1922 the Department of Labor and Industry of the Commonwealth of Pennsylvania has issued a monthly bulletin, its expressed purpose being "to conserve, to standardize, and to present, in readable form, the current information that emanates from the Department of Labor and Industry." It is thought that the publication of a monthly bulletin will get this information forward so that it will be immediately effective, and hence be of much greater value than the publication of yearly reports.

The National Tuberculosis Association has arranged for the publication of fourteen health plays, and has prepared a 6-page leaflet describing twenty-six plays, including these, issued by the various health organizations. The plays have been prepared to suit different age groups from primary school grades to high school, and several are adapted for use by clubs or community groups. The Association has a new film designed to teach health habits to the child of the slums, entitled "The Kid Comes Through." It is also distributing a dental hygiene film in three reels, produced by Colgate and Company, which may be borrowed free of charge except for transportation.

The case of a window cleaner who was arrested and jailed because he failed to use in the course of his work the safety belt provided by the employer is reported in *The Industrial Bulletin* issued by the Industrial Commissioner of New York State, Albany. This is the first time an employee has been arrested and punished for failure to use a safety device. Criminal proceedings are likewise instituted against employers who fail to provide safety devices for their workers.

A satisfactory demonstration of the effectiveness of compulsory education and the Child Labor Act in Pennsylvania is evidenced by the report of the Bureau for May. Only 254 persons out of the 1967 registered for rehabilitation are under 21 years of age and not one of these is without some schooling. According to the figures submitted on the educational qualifications, it is shown that those who had the least amount of education before their injury are foreign born. Most of the foreign born rehabilitation cases were laborers, while most of the American born were skilled or semi-skilled.

**CHILDREN'S  
SHOES**  
that are  
*Scientifically  
Designed*

**M**ANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed. Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

***Certainty of Quality  
Promptness of Service***

There is frequently an urgency in the requirements of a Public Health Department, Dispensary, Industrial Hospitals and Surgeons in charge of the health groups, that calls for more than ordinary cooperation on the part of the supply house. Likewise there must be a positive assurance of the quality of each and every item.

With a full appreciation of these conditions the Chemists Supply Co. seek the patronage of these groups. Intelligent service is given on every order; the quality of our product satisfies the most exacting. The various chemicals, vaccines, solutions in ampoules, drug specialties and kindred supplies used daily or in an emergency, are at all times available, in necessary quantities.

*Try us in an emergency—Your satisfaction  
will assure your routine business.*

### Roberts and Kelly on Fractures

It seems strange that in that field which was among the earliest explored the greatest progress should have occurred only within the last few years. The pathology of fractures was fairly well understood by the ancients. Since historic times the fundamentals of the treatment of fractures have been approximation of the fractured ends of the bone and immobilization to maintain this approximation. The fundamentals have remained, but numerous new details have been added, details of sufficient importance to change to a great extent the general course of treatment. As a result of the war, clinical material in enormous abundance was available and various methods of extension, maintenance of apposition, active and passive motion could be put to a practical test. It is therefore fitting that a book on fractures should be revised and knowledge gained during the war incorporated. John B. Roberts and James A. Kelley's "Treatise on Fractures in General, Industrial, and Military Practice" is a good book and we are glad to note that it is being kept up to date. The authors have revised and amplified this second edition so that it contains the advances in our knowledge of the treatment of fractures.

J. B. Lippincott Company, Philadelphia, 1921.

### The Epidemiology of Tu- berculosis

In "Epidemiology of Tuberculosis" Dr. George E. Bushnell aims to collect and discuss facts regarding epidemiological data which have been published in widely scattered and often more or less inaccessible periodicals and, the greater part of them, in foreign tongues concerning tuberculosis and its relation to the human race. In its first draft this volume was an essay on tuberculosis of the tropics and the Negro race. Dr. Bushnell has enlarged it to its present volume.

He considers the era before Koch's discovery of the tubercule bacilli and in a separate chapter the modern era of tuberculosis. He draws a distinction and discusses the races which have been tuberculized and those which he classes as non-tuberculized races.

He takes up the pathology and pathological anatomy, modes of infection, diagnosis, especially tuberculin diagnosis, and prophylaxis of the non-immunized individual. He

then considers the treatment of tuberculosis in the tropics, tuberculosis as it affects the American Negro and the American Indian.

He closes this book with a chapter on some practical considerations and finally summarizes and concludes his opinions on the general subject. On the whole in this volume he makes a plea for accepting the inevitable tuberculization of the human race as brought on by modern civilization. There seems to be, in his opinion, no escape from this without more radical changes in our mode of life than can be reasonably anticipated. There is no reason for alarm in that the modern world is a tuberculosis world but probably the reverse. He believes that our aims should be to have the already large percentage of our children who are already immune to tuberculosis increased to 100 per cent. Better care of the infant and the inauguration of an intelligent instruction of the mothers is the best way in which so happy a state can be approximated.

This book is full of sound, sensible philosophy.

—J. B. HAWES, 2ND.

William Wood & Co., New York, 1921.

### Joslin's Diabetic Manual

Joslin in the second edition of his "Diabetic Manual" explains in simple language the present conception of diabetes and the treatment for the disease. In his endeavor to make the subject plain to the patient nothing of scientific value is omitted and consequently the text is worthwhile for the physician. Pertinent facts are given to show the recent improvement in diabetic treatment. Scientific questions of import to the patient are asked and answered in such simple terms that any individual of ordinary intelligence can grasp the points. A chapter on diabetic arithmetic explains the computations involved in selecting dietaries of the proper proportion of the various food stuffs. Full descriptions are given of the diets for diabetics. Some explanation is made of the rôle played by carbohydrates and fats and the consequent necessity for controlling the intake of both these substances. Dietetic suggestions with definite recipes and menus are recorded. The information contained in this book is of value to any diabetic or any one interested in the disease. Certainly if the instructions laid down in this manual are carried out the diabetic can lessen his pitiful plight and prolong his life.

Lea & Febiger, Philadelphia, 1919.

### Cunningham's Practical An- atomy, Volume 3

Cunningham's "Manual of Practical Anatomy," the third of the "two little green books," as most of us remember them from our freshman dissection days, has appeared, thus completing the new series of three. Volume 3 deals with the anatomy of the head and neck. The same improvements noted for Volumes 1 and 2 apply to Volume 3. The x-ray plates are a great help to the student in correlating the subject. The distinctive indented type for the instruction for dissection facilitates the use of the book as a dissecting manual. The reviewer, as was noted in the reviews of Volumes 1 and 2, is pleased to see the insertion of the B N A nomenclature along with the old terminology. This is the more exact of the two and its universal adoption is desirable.

William Wood & Co., New York, 1922.

### Metabolism and Growth from Birth to Puberty

Francis G. Benedict and Fritz B. Talbot have been pioneers in the field of metabolism in children. It is partly due to them that general interest of the profession in metabolism has been aroused. Their monograph on "Metabolism and Growth from Birth to Puberty" will undoubtedly serve as a standard for all workers in the field.

Carnegie Institution, Washington, D. C.

### Submucous Resection of the Nasal Septum

The student of rhinology will find a valuable contribution to his library in the small book by William Meddaugh Dunning on "Submucous Resection of the Nasal Septum." The treatment of the subject in such complete detail under a single cover will be welcomed by beginners in the specialty. Under separate chapters are discussed the anatomy, physiology, and surgical procedures which are indicative in ordinary and complicated deviations. The indications given for operative interference are thorough and conservative, and are followed by a regimen of sensible after treatment. There are numerous illustrations which are helpful from the didactic standpoint.

There is little to interest the practising specialist. The text describes the technic of the author, and conflicts at times with the methods of others performing successful resections.

The Surgery Publishing Company, 1921.

## Etiology and Pathology of Typhus

This handsome volume of 222 pages and 34 plates by S. B. Wolbach, John L. Todd, and F. W. Palfrey forms an impressive monument of the first phase of the history of the League of Red Cross Societies. This organization in response to the exigencies of post-war economy has now been transformed into a relatively small but effective organization for the co-ordination of the practical peace-time work of Red Cross societies, but during its first few years through the generous support of the American Red Cross it was able to undertake fundamental and important activities along the lines of original research. The most valuable of these studies was the trip of the typhus research commission to Poland in 1920-21. The results here presented by the distinguished group of investigators in charge mark a landmark in the history of the disease with which they deal. The work of daRocha-Lima and other previous investigators had made it highly probable that the causative organism in typhus fever was a *Rickettsia* but the careful pathological work of Dr. Wolbach and his colleagues has added by far the most substantial evidence available in support of this view. The demonstration of *Rickettsia prowazeki* in the louse and in human typhus and the distinction between this organism and other types of *Rickettsia* is highly convincing and the presence of *Rickettsia pediculi* in lice found upon a patient suffering from trench fever strongly suggests that the causative agent of this disease has also been discovered. The experiments conducted in Warsaw are admirably and clearly presented and the plates are of unusual beauty and clearness.

C.-E. A. WINSLOW.

## Textbook of Embryology

The "Textbook of Embryology" by Frederick Randolph Bailey and Adam Marion Miller has reached its fourth edition in the twelve years since it first appeared. Meanwhile it has become one of the standard text books on the subject. The authors originally wrote the book for medical students and in each new edition have not only added enough new material to bring it up to the standard of recent knowledge but have also simplified the work so as to make it suitable for the student of medicine. In order to further interest in the subject the authors have added at the end of each chapter the most important references on the subject discussed, so as to give the student easy access to the literature. The illustrations in the book are exceptionally clear. The book deserves the popularity it enjoys.

William Wood & Co., New York, 1922.

## The Vitamins

"The Vitamins" by H. C. Sherman presents a condensed account of recent vitamin studies and summarizes with sufficient detail all of the important work of the past ten years. The first chapter is an historical survey of the field; Chapters II to IV deal specifically with vitamins B, C, and A, respectively, setting forth all that is most important in our present knowledge of the three and bringing out the necessity of quantitative experimentation in vitamin researches.

The final chapter of the book makes a highly practical application of the nutritional characteristics of our different staple articles and types of food. A table is given which indicates the relative values of foods as sources of vitamins. Keeping in mind the economic questions involved in the average family dietary, he gives as a

"rule of thumb" for insuring a dietary fairly balanced as regards mineral elements and vitamins, without detailed planning on the part of the housewife, the plan of budgeting the expenditures for food to see that at least as much is spent for vegetables and fruit as for meats and fish, and at least as much for milk in its various forms as for all forms of flesh food. Since this suggestion does not attempt to fix the relation between expenditures for these foods and for breadstuffs it is applicable at any level of expenditure for food. The authors suggest, however, that the facts have been learned from the standpoint of the wise utilization of food resources as a means of promoting the best nutrition of the people as a whole which should be put to work.

Accordingly, the chief groups of food are reviewed from this standpoint. They conclude with the statement that even with our present knowledge with reference to vitamins and other nutritional needs, "with a dietary selected to make the best use of our staple foods there will rarely if ever be occasion to purchase vitamins in any other form, or to give any greater anxiety to the vitamins than to some other factors that enter into our present conception of nutritive requirements and food values."

The Chemical Catalog Co., Inc., New York, 1922.

## Complete Index to Keen's Surgery

Just as a ship is useless unless it has a rudder for guide so is a compilation of knowledge of little value without an index. The index to Keen's Surgery is the final touch in bringing this great work up to date. All eight volumes are carefully and fully covered.

W. B. Saunders Company, Philadelphia, 1921.

## INDUSTRIAL NURSING

**S**PECIAL qualifications are demanded of the industrial nurse and these qualifications vary in different plants. For this reason care and intelligence must be exercised in selecting a nurse who will meet the conditions in a certain industry and who will likewise be completely satisfied.

This careful service of selection is one of the principle reasons why Aznoe's service is recognized as particularly valuable in securing the proper industrial nurse for a firm and likewise placing the nurse in a position where conditions are satisfactory to her. Where Aznoe's service is used, both the individual and the employer are satisfied.

Let us send you our booklet giving the full details of Aznoe service, which is also available to industrial surgeon and to plants requiring the services of industrial surgeons.

### Food Products, Their Source, Chemistry, and Use

The more recent advances in the science of nutrition and in the art of food manufacturers are recounted in "Food Products, Their Source, Chemistry, and Use," a book by E. H. S. Bailey, the second edition of which has been revised and enlarged. It is non-technical in character and presents an interesting and remarkably accurate discussion of the nutrient and dietetic values of foods, their preparation, and their economic selection.

It is to be recommended as a textbook for courses in colleges and high schools and as a handbook for health workers.

P. Blakiston's Son & Co., New York, 1921

### The "Textbook of Histology"

The "Textbook of Histology," by Frederick R. Bailey has become a standard. Both the text and illustrations are very vivid. The Sixth Edition contains also a splendid chapter on the nervous system written by Dr. Oliver S. Strong. The references at the end of each chapter add considerably to the value of the book.

William Wood & Co., New York, 1920.

### Elements of Surgical Diagnosis

The fifth edition "Elements of Surgical Diagnosis" by Sir Alfred Pearce Gould and Eric Pearce Gould has been written since the world war and contains the advances made in surgical diagnosis during that time.

The reviewer has found the little book especially helpful in preparing his student clinics and lectures. The emphasis is laid on such diagnostic procedures as palpation and inspection rather than on laboratory tests. The author evidently feels as does the reviewer that the tendency at present is that the clinician is more apt to go to the laboratory to have a ready-made diagnosis, than use the laboratory simply as one of the many resources at his command.

Paul B. Hoeber, New York, 1920.

### Boyd's Cerebro-Spinal Fluid

It is interesting to note that within a period of two years two books have appeared on the subject of cerebro-spinal fluid. The book by Boyd, "The Physiology and Pathology of the Cerebro-Spinal Fluid," unfortunately does not cover the subject completely. It leaves out many facts gained by the profession in the last few years. It

pays little attention to the chemistry and physical chemistry of the fluid. The references are far from uniform. In some places the author gives the journal and the year in which the article is published and in other places the page and volume number. In spite of all this, the book is interesting in that an attempt is made by the author to give a review of the subject.

The Macmillan Company, New York, 1920.

### Binnie's Regional Surgery

To quote from the preface of John Fairbairn Binnie's Treatise on Regional Surgery "the aim of the present work is to present short treatises on the injuries and diseases of the different regions of the body. Binnie has well accomplished this. The collaborators are men of reputation gained for a great part in the field in which they write. For example in volume 1, Charles Mayo writes the chapter on the thyroid, Sam Robinson on the surgery of the heart, pericardium and diaphragm, Chevalier Jackson on the removal of foreign bodies from trachia and bronchi, and Joseph Colt Bloodgood on the breast.

The text is well illustrated, the descriptions clear, and concise.

P. Blakiston's Sons, Philadelphia, 1922.

## IN ACIDOSIS

All the bases of the body are drawn upon (not only sodium) and lost from the body. When only sodium bicarbonate is given the loss of the other bases is not made up.

The use of KALAK WATER makes possible the administration of the several bases in agreeable form—an important matter when patients must take alkalies for longer periods.

Each bottle carries in sparkling form several grammes of the bicarbonates of sodium, potassium, calcium and magnesium.

## Eugenics in Relation to the Deaf

Curative Measures Have Advanced, But Can Not Keep Pace With Hereditary Deafmutism

BY EMIL AMBERG, M.D., F.A.C.S., DETROIT, MICH.

LET us consider that there are many people in this world who have never heard the word "Mamma," who never enjoyed the singing of the birds and the songs of man, the ear-essing voice of the mother, the music of a silver-tongued orator, the pleasing and uplifting melodies by a great artist, or the stirring strains of an orchestra. "Viva voce" (with a living voice) is a significant expression, for a part of the world is dead to the deaf. The prevention of the dire affliction of deafness has been the aim of physicians for a long time. Owing, however, to the fact that the organ of hearing is so very delicate, that it is hidden deep in the head, and, that the development of curative measures in ear diseases has to a great extent taken place only during the last few generations, it is little wonder that the important subject of eugenics and dysgenics of the hearing apparatus is of comparatively recent origin.

The efforts to prevent deafness after birth are not subject of this article. It is a great field which is receiving much attention at present, and is of the utmost importance. We may ask ourselves two questions: (1) Is there any reason for the assumption that heredity plays a part in deafness? (2) Can anything be done to avoid, or, to correct the influence of heredity?

Concerning the first question let us hear what some observers and au-

*The alleviation of the condition of the deaf is a medical problem to the extent that the defect in a given case may be open to medical cure.*

*In all other aspects it is a social problem, for if a deaf-mute is ever to become a useful member of society it is only through far reaching social measures of welfare work and highly specialized education.*

*An indispensable part of any control of the situation is a study of the causation of deafness, and its logical remedy through eugenic measures.*

thors say. A publication by the Volta Bureau in Washington entitled "Marriages of the Deaf in America," by Edward Allen Fay, Washington, D. C. 1898. is frequently quoted. Fay's investigations have been made the subject of a critical study by Alexander Graham Bell.

Fred DeLand, superintendent of the Volta Bureau, in his introduction of the "Graphical Studies of Marriages of the Deaf" by Alexander Graham Bell, 1917, says that Dr. Bell followed up the good work started by Dr. Fay and found:

Marriages resulting in deaf offspring ..... 300  
Total number of children born...1,044

Number of deaf children..... 585  
Proportion deaf .....56 per cent

In other words, from these three hundred marriages that resulted in deaf offspring more than half of the children born were deaf.

Another development worthy of note is that of these 2,642 marriages analyzed the average number of children per marriage in the three hundred marriages that resulted in deaf offspring was 3.48, while an average of only 2.44 per marriage was reported in the 2,342 marriages resulting in no reported deaf offspring.

Alexander Graham Bell has also expressed himself as follows:

(1) A deaf person not born deaf, who has no deaf relatives, will probably not increase his liability to have deaf offspring by marrying a blood relative.

(2) A deaf person born deaf, who has no deaf relatives, will probably increase his liability to have deaf offspring by marrying a blood relative, especially if that relative should happen to be on the deaf side of the family; for example: If his father has deaf relatives and his mother has none, he will more likely to have a deaf offspring if he marries a relative of his father than if he marries a relative of his mother.

Speaking in general, Bell says, "As there are few families entirely free from constitutional defects of some kind, a prudent person would do well to avoid a consanguineous marriage

in any case, not necessarily on account of deafness but on account of the danger of weakening the constitution of the offspring."

Hammerschlag examined 237 pupils of an Israelitic deafmute institution. There were 168 marriages with one deafmute child; blood-related were twenty-four, or 14.3 per cent; twenty-eight marriages with each two deafmute children; blood-related were eight, 28.57 per cent; fourteen with three or more deafmute children; blood-related were eight, i. e., 57.14 per cent. "If therefore," Hammerschlag concludes, "the multiplicity of the occurrence is a criterion of hereditary deafmutism—and that is not doubted by any author—then the increase of the relation of marriages of deafmute parents related by blood found in these observations, furnishes a weighty proof that blood-relationship plays a part in the cause of congenital deafness."

H. Herzog, Innsbruck, very clearly distinguishes between inherited and congenital deafness. He calls heredity the repetition of parental qualities in children and children's children by virtue of a transmittable mass in the egg or sperm-cell. Therefore he speaks of hereditary deafmutism only if it stands in causative relation to the same defect in an ancestor. He adds that the expression "hereditary" might better be avoided because it is ambiguous, e. g., we speak of hereditary syphilis and designate thereby a disease acquired in the womb. The conception, continues Herzog, that otosclerosis can be attributed to an inherited cause, has found more and more adherents until Hammerschlag has proved it scientifically. The family trees which he and Koerner studied illustrate the transmission of the defect partly to the fourth generation.

Boeninghaus quotes Siebenmann, who attributes a large number of congenital (this is not hereditary) deafness to meningitis, or, perhaps, to a primary inflammation of the hearing nerve. We do not know whether these affections occur after birth, in the first year, or, whether they occur in the womb through placentary infection of the unborn as it is partly proved in typhoid fever, influenza, pneumonia, and mumps of the mother. A small percentage of cases of congenital deafness is caused by malformation of the inner ear.

#### Predisposing Causes

Boeninghaus claims that predisposition for the defective initial lay of the inner ear is caused particularly

by marriage of blood relatives. Here it occurs frequently that several children are deafmutes. Also deafmutism of one or both parents is predisposing, yet, strange to say, the predisposition is not great, even if we consider that only a small portion of deafmute parents may possess a defective initial lay of the inner ear, which is transmittable. This strange phenomenon stands in sharp contrast to the experiments with breeding of congenitally deaf animals, Angora cats, Dalmatian dogs with white skin and blue eyes, and Japanese dancing mice. Yet, we must consider that these deaf animals are produced by breeding of deaf parents, probably through generations. The heritability of abnormal initial lays must be exceptionally great under such cir-

This picture is reproduced from an illustration contained in a booklet on "The Conservation of Hearing," by Eduard Semal, 1837. While it is old and somewhat diagrammatic, it gives an excellent idea of the location of the hearing organ, deep in the head and near the brain. The instrument, introduced through the nose, points out the Eustachian tube, which connects the throat with the ear, while the probe L is carried through the outer ear canal.

cumstances. Predisposition is also caused by deafmutism in the sideline.

Koerner states that congenital deafness is caused either by an arrest of development of the labyrinth (aplasia), or by a congenital degenerative atrophy, i. e., wasting away of the acoustic nerve, or by a disease of the labyrinth occurring before birth. In the latter instance, we have as a rule a degeneration and metaplasia (change of one kind of tissue into another), of the endothelium in the endolymphatic space, i. e., of the lining of the space in which the delicate hearing organ proper is located. The labyrinthitis after birth affects children most frequently when they are from two to four years old.

Wittmaack in his book on otosclerosis says that the influence of heredity can be named also for the development of local changes. If the soil is prepared, general causes may be an

auxiliary factor (syphilis, tuberculosis, infectious diseases, gout, extension of pneumatization.) Other characteristics (time (a ce. the color etc.), so to acquire otosclerosis who are distinguished from the other members of the family by these irregularities.

S. MacCuen Smith says, in emphasizing the heredity factor, that he knew from personal observation of a certain family which for several generations back had presented the tendency to otosclerosis, that all the descendants who resembled in features or traits a certain paternal ancestor, uniformly had begun to lose hearing at an early age, of about seventeen or eighteen years, and nothing stopped the progress of this tendency, although the family were well off and neglected no means to prevent it.

Kerrison says, concerning heredity, that Hartmann (Berlin) reports two families in which the parents were congenital deafmutes, and that of five children born to them four were deafmutes. The parents who suffered from acquired deafmutism had children with normal hearing. Love (Scotland) reports three families with congenitally deaf parents. Among the children of these three families were five congenital deafmutes. Love mentions that among the Roman Catholics in Germany whose church prohibits intermarriage between near blood-relations, the proportion of deafmutes to the rest of the Catholic population is 1:3000, with Protestants, by whom intermarriages between cousins is not condemned, the proportion is 1:2000 while among the Jews who encourage intermarriage between blood-relations it is 1:400 (Hutchinson).

Dr. Hays of New York is of the opinion that hereditary deafness can be claimed only in those cases in which there is deafness among ancestors in direct line. One or two generations may have been skipped, but that one will find many cases of hereditary deafness which are directly traceable, that congenital deafness is a deafness which develops before the child is born and that it may be due to a true congenital defect or to syphilis in one or both parents.

Baratoux gives the following changes in the syphilitic newborn: purulent middle ear inflammation, thickening of the drummembrane and the latter melted to the inner ear (promontorium); in the inner ear: hyperemia (i. e., congestion), hemor-

rhage, collection of pus and breaking down of the organ of Corti. Hereditary syphilis of the labyrinth, according to Politzer, is often combined with adhesive processes in the middle ear.

We must also take into consideration that, just as facial traits are transmitted, so is the configuration of the inside of the nose and of the throat. Inasmuch as the nose and throat stand in direct relation to the ear it is only natural to assume that, in transmitting a disadvantageous anatomical condition, also the ear of the offspring may be influenced. The parents, teachers and the nurses must especially be on the lookout for children who show any abnormality which suggests the possibility that a nasal obstruction exists or that adenoids and diseased or hyperplastic tonsils are present. Proper adjustments of these conditions may counteract transmitted faults, to a greater or less extent.

In answering the question whether anything can be done for the hard of hearing, we readily see that eugenics plays a very important part, and the avoidance of the evil influences pointed

out in the foregoing paragraphs suggests the remedy.

In conclusion I may add that it is understood by itself that everything medically possible must be done for the hard of hearing and for the deaf. Besides, when the hardness of hearing has reached such a degree that it interferes with the relation of the individual to society, lip-reading should be taken up. There exist excellent schools for the deaf in many places in the country. Adults can also obtain the benefit of such instruction in many places. It is especially recommended that deaf adults should join the societies for the hard of hearing, which exist in great numbers. Aside from the benefits accruing to the members concerning instruction and economical help, the social aspect is of incalculable assistance to the mind, replacing the feeling of loneliness and partial uselessness by the firm conviction, that also the deaf person fills a definite place in society, that there are occupations in which his or her services are preferable, and, that the opportunities for social enjoyment are by no means closed to the deaf.

## Business Introduces Health

WE ARE not unaccustomed to child welfare and humanitarian groups throwing the searchlight of investigation on commercial enterprise and products. Popular interest in health is such that some business is under scrutiny most of the time, and surveys, studies, and reports flood the health worker's desk. Notably the dairy interests and dairy products have been the object of criticism and recommendation by such committees of investigation, but now the tables are turned and we see the spectacle of the dairy industry making a specific study of the health stations and sanitation methods for which bureaus of child hygiene are responsible. A Committee representing the London Dairies, Ltd., of London, England, is now on tour of the United States making this study preliminary to the adoption of pasteurization of milk in London; and they expect to aid in the broad extension of stations for the saving of countless children's lives in England.

It is not said whether this investigation is primarily concerned with the saving of lives or with finding a larger output for dairy products through health centers, child welfare agencies, and schools, nor does the

motive weigh very much in the matter if in the end the children receive added rations of vitaminized and pasteurized milk.

American industry is not outdone in this matter, for we have in Health Week to be observed October 23 to 30 throughout the country an example of unparalleled health activity on the part of commercial groups. Representing, they say, the best of scientific achievement in health installations that promote better practices in personal hygiene, ventilation, and sanitation, they have not found that intelligent cooperation on the part of the buying and building public which means cleaner and better homes, newer and simpler means of ventilation, or anything like a general appreciation of the installations that save time and drudgery and thus afford more freedom and better energy for educational and recreational activities. Hence they propose during Health Week to unite all agencies in mass meetings for health, to line the thoroughfares with health displays, all carrying home the connection between daily practices and preventable disease. State and national health agencies will supervise the work to see that it is trustworthy.

Nor is this the first time that effective cooperation in health activity has been achieved by interested parties. The Metropolitan Life Insurance Company on its own initiative instituted perhaps the broadest program yet undertaken in industrial hygiene and health education of industrial groups, and the same company is responsible for our most extensive social research and our most searching analysis of vital statistics. The fact that the method of conservation put in practice by this company has effected a gain of about two hundred per cent on their investment in the work does not detract in the least from its value as a life saving enterprise and its importance as a health demonstration.

Speaking of the health activities of the Prudential Life Insurance Company recently, one of their officials asked: "Is it more creditable to pay a family ten thousand dollars on the life of the father, or to save a \$100,000 life for the family?"

We are a commercial nation. The life of any productive member of society has a definite money value. Health as an asset appreciates as we count the cost of ill health. The inventions that have been devised to make possible our highly complex modern life are factors of health. Let us learn more about them and about health maintenance in general. The ethical dealer who studies his public succeeds to the degree in which he meets the vital needs of the people. Let the fact that health cannot be divorced from any of the manifold activities of life be the message of Health Week.

## Nations Interchange Sanitary Staff

The first interchange of sanitary staff arranged by the League of Nations health committee will begin this month. This takes the form of a two weeks' course at Brussels for foreign public health officers followed by two months of first hand observation of the actual working of various public health systems. The twenty officials taking the course are drawn from the health services of Belgium, Bulgaria, Czecho-Slovakia, Italy, Poland, Soviet Russia and Ukraine, and the Serb-Croat-Slovene state.

At the fourth session of the health committee of the League of Nations it was decided in principle to send a small commission of inquiry to the Far East to study the prevalence of cholera and plague in ports.

# Community Medicine in the American Colonies\*

## Midwives and Trading Vessel Surgeons Furnished Medical Aid to First Settler

BY ELIZABETH C. TANDY, M.A., COMMITTEE ON DISPENSARY DEVELOPMENT OF THE UNITED HOSPITAL FUND, NEW YORK CITY.

RECORDS of the first attempts at colonization in America show that whole colonies were wiped out by Indian massacre and disease. What the Indian did not destroy, starvation and fever finished off. When the vessel which was the last visible link that tied the emigrants to their native land sailed away with the ship surgeon on board, the colonists were thrown upon their own resources. They had no professional assistance in caring for their individual or community health. If an epidemic struck them the Indian medicine man of the nearest tribe would be more likely to work charms against them than to help stay the ravages of the disease. In these disastrous experiments at colonization it is little wonder that sickness ran a close second to the scalping knife.

It is well to remember in considering the health protective measures of later colonial days that settlements were for the most part commercial enterprises, controlled and financed by commercial companies, whose primary interest lay in the speedy return of the original investment at a high rate of interest. The proprietary charters granted by royal prerogative to these trading companies charged them with no responsibility for the general health or well being of the loyal subjects who undertook their ventures. Emigrants of all kinds were thrown upon the mercy of the companies. Respectable people seeking religious liberty, freedom from debt, a chance to make a new start were given no safeguards against the exploitation of their physical reserves. Frequently, as in the Plymouth Colony, a group entered into the relationship of bound servant to a corporation intent only upon the amassing of wealth. Although colonizing schemes in Virginia

had been repeatedly wrecked by sickness, lawmakers with characteristic irresponsibility ignored the whole problem. Colonists received no health protection from the crown or parliament.

It is to the everlasting glory of all the early trading companies that they made provision for the medical care of the pioneers who undertook their ventures. Before the Massachusetts Bay project was fairly launched in New England the question of a medical man to accompany the planters was discussed by the Company. At one of its earliest meetings held March 5, 1628, it is recorded that:<sup>1</sup>

A Proposicion beeinge made to Intertayne a surgeon for the plantacon, Mr. Pratt was propounded as an abell man up (on) their condicon Namely That 40 pound should bee allowed

The American colonists were dependent solely at first on barber surgeons, midwives, and trading vessel physicians for medical care.

him, vizt for his Chist 25s, the Rest (for) his own sallery for the first yeere puided yt he (continue) 3 yeeres in the Comp to be at charge of transporting his wife and a ch(ild) haue 20<sup>a</sup> yeere for the other 2 yeeres and to build him a ho(use t) the Comp. Charge and allott him 100 acr of ground, but if he stay but one yeere then the comp. to bee at charge of his bringing back to England and he to leaue his su(ant) and the Chist for the Comp. seruiice.

Agreed with Robett Morley s(r)uant to Mr. Andrewe Mathewes late barber surgeon to seue the Comp. in Newe England for three y(ears), the first yeere to haue 20 nobles, the second yeere (30<sup>a</sup> and the third) yeere 20<sup>a</sup> markes, to serue as a barber and a surgeon on all ocaseyons belonging to his Calling to aney of this (Company) toiat are planters or their

seruants, and for his (Chist and) all in it where of he hath guuen an Inuentory—sight of it bee approved fyve pounds is—and payd to him forr it and the same to bee fo(rthwith payd).

The Dutch West India Company showed similar foresight for their colony at New Amsterdam. In the Charter of Privileges to Patroons adopted June 7 17, 1629, appears provision which was intended to encourage private individuals to establish settlements:<sup>2</sup>

The Patroons and Colonists shall in particular, and in the speediest manner, endeavor to find out ways and means whereby they may support a Minister and a Schoolmaster, that the service of God and zeal for religion may not grow cool and be neglected among them, and they shall for the first procure a Comforter for the Sick there.

Dr. Lawrence Bohune<sup>3</sup> who came to Virginia in 1610 with Lord Delaware and cared for the Colonists in the "starving time" was created first Phisition Generall of the London Company at a session of the General Court held December 13, 1621. He was allotted "500 acres of land and twenty Tenants to be placed thereupon att the companies charge." Diligent search has not shown whether Samuel Fuller bore any official relationship to the Plymouth Company. As he was a friend of William Bradford at Leyden, a signer of the Mayflower Compact, and a deacon in John Robinson's church, it is improbable that he was other than a fellow voyager, a seeker after religious liberty. Contemporary accounts of Colonial history show him going from town to town at the request of governors, caring for the sick stricken with epidemic small pox and scurvy.

The history of colonial medicine also presents very distinct community aspects. Medical men were few in provincial America. Many of the physicians and surgeons who came over preferred the society of their professional confrères in England and soon returned. Most of the early colonies were for considerable periods dependent upon the barber surgeons and physicians of the trading vessels that

\*Author's note: These woodcuts furnished through the courtesy of the New York Public Library are by Dr. Alexander Anderson, "The Father of American Wood Engraving," 1775-1870. At the time of the yellow fever epidemic in 1795 he became resident physician at Bellevue hospital and later served as physician at the New York Dispensary at a salary of one thousand dollars a year. In 1796 he received the degree of Medical Doctor at Columbia College. These woodcuts represent the spirit and practice of medicine in provincial America. Art in the American colonies was very limited, and I am informed that I am exceedingly fortunate to get these illustrations. E. C. T.

2. MacDonald's Select Documents, Vol. 1, p. 50.  
3. Cyc. of Medical Biography, ed. H. A. Kelly, Vol. 1, pp. 13, 94.

Midwives were the sole dependence of the pioneer women in confinement. Not until after the middle of the eighteenth century was the practice of men in obstetrics regarded with favor.

visited the coast. It was customary for governors to attempt to secure medical attendance from more fortunate colonies whenever epidemic conditions arose. At a slightly later date we see neighboring communities making group contracts with medical men and offering them substantial inducements to settle in their part of the country. An instance which appears in the Town Records of Deerfield, Mass.,<sup>4</sup> shows the nature of the arrangements and the method of financing the institution:

Passed Mch. 27th, 1739.

Voted that Mr. John Catlin be appointed to go to Hatfield and meet the Committees of Northampton, Hadley, and Hatfield and there in behalf of this Town to act and determine what to give Dr. Potter for his encouragement to settle as a bone setter in this part of the country; that is to say whether to give him fourteen pounds or what part soever there of shall be by him accounted to be our proportion with ye rest of the towns, considering ye circumstances of ye town with regard to their distance from him; and what he shall agree for the town will and do hereby order to be raised for him in a rate on the town, to be raised according as ye Law directs for ye raising of Town Taxes.

Early in the history of New Netherlands we find special arrangements made with regard to midwives. Lisbert Ducken was the town midwife of New Amsterdam in 1638. A house was built for her at the public expense by the direction of Governor Van Twiller. "In 1644 Tryntje Jones, the mother of Annitje Jasz, was the midwife of the town. She died in 1646 and the daughter had some difficulty in collecting from the Dutch West India Company certain monies due for the mother's services. In 1655 Hellezord Joris was appointed midwife to the town, and in 1660

Council voted her a salary of one hundred guilders a year for attending the poor."<sup>5</sup>

The following quaint epitaph<sup>6</sup> found in the Phipps Street burying ground at Charlestown would seem to indicate that midwifery had somewhat similar community aspects in Massachusetts.

Here lyes Interred ye Body of Mrs. Elizabeth Phillips, Wife to Mr. Eleaser Phillips, who was born in Westminster in Great Britain and commissioned by John Lord Bishop of London in ye Year 1718 to ye Office of a Midwife; and came to this country in ye year 1719 and by ye blessing of God, has Brought in this world above 3000 children. Died May 6th, 1761. Aged 76 yrs.

In the Plymouth Records<sup>7</sup> another evidence is found:

On the 2d of January, 1710 there was a Meeting of the women of the Town Warned by the Authorities to make Choyce of som of sd women of sd town for Midwives and after they had given in their votes the lot fell to those following (viz)

- Lidish Rider
- Judith Ffaunce
- Susanne Coole
- and Anna Stirlevant.

These early midwives were the sole dependence of the pioneer women in confinement. It was well after the middle of the eighteenth century before the practice of men in obstetrics was regarded otherwise than with popular disfavor. The first record of a man officiating in the capacity of an obstetrician of which we have information is to be found in the death notice on July 22, 1745, of Dr. John Dupuy of New York City:<sup>8</sup>

Last night, died in the prime of life to the almost universal regret and sorrow of this city, Mr. John Dupuy, M.D., a man midwife, in which last

character it may be truly said as David did of Goliath's sword, there is none like him.

South Carolina<sup>9</sup> had trained obstetrical service dating from the year 1733. Dr. James Loyd<sup>10</sup> was the first systematic practitioner of midwifery in Massachusetts. He settled in Boston in 1754. Two years later Dr. William Shippen, another scientifically trained accoucheur settled in Philadelphia. These were the American pioneers in that branch of medical science which has latterly been recognized of primary importance. Untrained midwives reigned almost supreme in the realm of colonial obstetrics. It was only at the very end of the period that their authority was challenged.

The ministerial physician, or the "angelic conjunction" of Cotten Mather, flourished in New England. It was customary for most ministers to have a little training in medicine and their habit of visiting the sick as religious advisers gave them ample opportunity for the observation of symptoms. Regular practitioners were occasional in New England, but more frequent in New York. Most of the scientifically trained physicians of the American Colonies had attended the universities of Holland and were acquainted with the best knowledge of the period. Well trained men, however, were few. The greater number of colonial practitioners received their training by apprenticeship. Great need of medical care, scarcity of physicians, and lack of facilities for instruction gave the natural opportunity for the development of a class of charlatans. Throughout the colonies quackery flourished with little let or hindrance. Most of the colonies passed laws which attempted to regulate medical practice and prohibit extortion. The conditions of colonial

life, however, minimized the beneficial effects and the negative alternative of discouragement to invention and experimentation was the primary result of this regulation.

Some women midwives seem to have belonged to the group of colonial medical practitioners. The first person executed for witchcraft in Massachusetts was Margaret Jones, "physician and doctress." Among the evidence of her guilt recorded by John Winthrop<sup>11</sup> we find that, "she practicing physic and her medicines being such things as (by her own confession) were harmless as aniseed, liquors, etc. yet had extraordinary violent effects. She would used to tell such as would not take her physic that they would never be healed and accordingly their disease and hurts continued with relapse against ordinary course and beyond the apprehension of all physicians and surgeons." Jane Hawkins<sup>12</sup> who delivered Mary Dyer of her monstrosity was, likewise a well-known midwife and physician. In the session of the Massachusetts General Court March 12, 1637-1638 this record appears: "Jane Hawkins the wife of Richard Hawkins had liberty till the beginning of the third mo called May, and the Magistrates (if she did not depart before) to dispose of her and in the meantime She is not to meddle in surgery, or physick drinks, plaisters or oyles; nor to question matters of religion, except with the elders for satisfaction."

Just after the middle of the eighteenth century opportunity for medical instruction began to develop in America. The medical college of Philadelphia was established in 1765, Kings College in 1768, and Harvard Medical College in 1783. People could now get scientific medical training without spending several years in Leyden or London.

With the establishment of medical schools in the colonies and the multiplication in the numbers of well trained private physicians the community aspects of medicine took a less important place. Settlements grew from compact little villages to groups of fair sized separate communities able to support independent practitioners. Legislation regarding the medical profession came to be restrictive rather than promotive. Official disputation over colonial health matters was to be centered about the wrangles between the crown and the General Assemblies concerning prov-

incial legislative authority for the regulation of local quarantine and nuisances.

In the question of medical care as in the other provisions for colonial welfare it is evident that the early colonists had for a time the spirit of community provision. As the size of

their settlements increased and the struggle for legislative power grew they lost sight of community in approaching democracy. It is interesting to see that as our ideas of democracy change we are getting back to community spirit, particularly in provision for public health.

## Army Water Purification Unit

THE purpose of the Army Water Purification Unit is to furnish an adequate supply of potable water at convenient points for the use of troops in the field. This requires a mobile unit of considerable capacity, yet one capable of meeting the modern high standards for potable water. The entire equipment of this unit is mounted on a standard Army 3½-ton Liberty Truck, and consists essentially of a single centrifugal pump rated at 100 gallons per minute against a 75-foot head, directly driven by a 4 cylinder gasoline engine, operating at 1150 revolutions per minute; a 42-inch, pressure, mechanical filter with a hand agitator; a five-way control valve; a combination direct dry feed and solution feed chlorinator with a capacity of .1 to 12 lbs. chlorine per 24 hours; an alum pot and a soda ash tank with appropriate feeds; a venturi meter and a simple laboratory for making acidity, alkalinity, color, turbidity and free chlorine tests.

The unit may be operated as a simple pump unit, as a pumping and chlorinating unit, or as a pumping and filtering unit with or without chlorination. A five-way valve is provided as a convenient means of control. The valve may be set to normal filtering, to discharge to waste, to

wash the filter, or to by-pass the filter. The alum pot supplies the alum to form the coagulant layer in the filter, and in case the water does not have sufficient natural alkalinity the soda ash tank contains a 3 per cent solution of soda ash which may be added to it. The chlorine is carried in tanks as a liquid under pressure and may be fed directly as a gas or as a solution feed with a Wallace & Tiernan Company Army type pulsating meter. The chlorine, alum, and soda ash are all added to the suction line to facilitate thorough mixing and to give a maximum time for the chemical reactions. Gauges and meters are provided to show the pressure and volume of the water.

This unit has been subjected to numerous road and field tests. Its mobility is the same as any loaded 3½-ton truck, and no material trouble has ever developed with the apparatus during the road tests. Field tests have shown that it has a normal capacity of about 4,000 gallons per hour and that it will deliver a clear, sterile, potable water from a turbid stream that is grossly contaminated with bacteria.

It will furnish enough potable water every hour to last one thousand soldiers one day.

An equipment devised to furnish potable water to troops in the field.

# Some Recent Advances in Sanitary Science\*

## Engineers Have Opportunity for Public Service in Sanitation

BY GEORGE C. WHIPPLE, PROFESSOR OF SANITARY ENGINEERING, HARVARD UNIVERSITY, CAMBRIDGE, MASS.

THE word "sanitation" has to do with the environmental side of health and connotes the idea of cleanliness. Clean air, clean water, clean food, clean clothing, clean houses, clean streets, clean rivers, clean soil,—all these and more are comprised within the compass of this word sanitation. From the public health point of view sanitation is limited to matters which affect a considerable number of people and which are usually undertaken by governments or are regulated by governments under the police power. These come within the field of the sanitary engineer.

There have been no sudden or spectacular advances in the science of sanitation during recent years. Some new ideas have come to the front, but for the most part they are of minor importance. Sanitary engineers appear to be especially interested just now in studying the results of operation of existing works with a view to making improvements in many matters which affect cost and efficiency. High prices and unsettled business conditions have caused a lull in construction. While a period of inactivity and retrenchment is never welcome, it gives everyone a chance to study and practice economy,—a process by no means unhealthful to the good of the cause.

Public health activities are based partly on science and partly on law, and the best results come from a proper blending of the postulates of both. This is a scientific age. The aeroplane and all sorts of wireless devices become accomplished facts while men were yet dazzled with amazement. But it is also a land governed by law, and laws are of slow growth. Sometimes the present efforts to combine science with law seem like putting new wine into old bottles. Occasionally the bottles burst and new laws or new interpretations of laws result. Often, however, the established legal principles hold fast, and it is a good thing for all concerned that they do. The United States Supreme Court has re-

*Service is always sacrifice. Our country never lacks for patriotic service in time of war. Young men should do as much for their country in peace time as they would do in war time. No one can do more to influence our best young men to take up public health as a life career than men who are already in it.*

*Is there not a joy in seeing death rates go down; in seeing preventable diseases disappear; in seeing streets cleaner and houses better in seeing cheeks rosier, muscles firmer, and backs straighter? Is there not a satisfaction, greater than that which comes from large money earnings, in feeling that one has had his little part in making the world a better place in which to live? And if this is so, why not tell it to the young men?*

cently handed down a decision that the Child Labor Law is unconstitutional, because it conflicts with the Tenth Amendment of the Constitution. The amelioration of the hardships of child labor is without doubt desirable and necessary, but the maintenance of the integrity of the Constitution, the great bulwark of our liberty, is far more important to the country. The Attorney General of Massachusetts has said that in his opinion the Sheppard-Towner bill is also unconstitutional, and steps are to be taken to bring this to decision. The Court of Appeals of Kentucky has decided that under the statutes the State Board of Health can forbid the furnishing by a company of impure water to a community, but can not direct the use of any particular method of purification. There are limits to a state's use of the police power. This power is properly employed to protect the people against injury but not to procure benefit, even though the benefit be for the public health,—a distinction often hard to make, but one of much importance. Dean Wigmore of the Northwestern Law School recently said, "Law and

science need to become better acquainted," and from the examples cited it is evident that this includes sanitary science. It is gratifying, however, to find that the general principles of our common law, statute law, and constitutional law prove adequate in the long run to bring to pass the really important sanitary reforms.

Similarly, it may be said that sanitary science and business,—or economics—need to become better acquainted. Once health officials said that "no expenditure of money for public health can be too great if a single human life is saved." The war gave a new conception of the value of physical life. In such a period as this when laborers lack work and when families go unfed, unclothed, and unsheltered, it is necessary to scrutinize carefully every dollar spent for health protection and for every other purpose. When it comes to a choice between more sanitation or more food, between more health education or more shelter, it is necessary to consider which is farthest below normal and which needs the dollar most. Even if it should be necessary to sacrifice temporarily something of public health, something of sanitation in order to maintain sound principles of government and justice, men should be willing to make the sacrifice, knowing that sound government and sound economics are just as important to the health and well being of the people as many of the public health activities of today. As a matter of fact, the three things go together and must not be considered apart,—sanitary science, law, and economics. These periods which compel governmental introspection, careful investigation of results, and perhaps retrenchment in appropriations can therefore be made of the greatest benefit to the cause of public health if they are used properly.

The early water purification plants were built according to ideas which developed from experiment. Filters have now been in use for ten, twenty, and thirty years, so that from now on engineers can base their designs on experience, a more trustworthy guide than experiment. The

\*Read at a meeting of the New York State Sanitary Officers, Saratoga Springs, N. Y., June 27, 1922.

success of water filtration in protecting communities against water-borne disease and furnishing a clean, wholesome water has been fully demonstrated. The cost of filtration has proved to be not excessive. The public does not object to paying for purity in its water supply. People are coming to believe, what the sanitary engineers told them many years ago, that all surface waters should be filtered. Even in conservative Massachusetts, where storage and the prevention of pollution have been relied upon to protect the water supplies, a joint board consisting of the State Department of Public Health and the Metropolitan District Commission recently said in a report on the water supply needs and resources of the commonwealth, "Natural safeguards have their limits. As time goes on, as the populations on the watersheds increase, it will be necessary to adopt a policy of filtering surface water supplies."

### Water Purification

A dozen years ago the method of disinfecting waters by chlorination came suddenly to the front. It has been adopted extensively, not only in scores of small cities but by the largest cities of the country. Unquestionably it has made a place for itself and demonstrated its usefulness. Its limitations are also being learned by experience. At one time it was said by some that the use of chlorine would make it possible to build filters more cheaply, using them merely as physical strainers and depending upon chlorination for bacterial purity. This false idea is being gradually cast aside. Chlorination cannot take the place of adequate filtration. It is false economy to slight the filtration process, because filtration with its accessory processes does more than remove bacteria; its function is to clarify a dirty water, decolorized a stained water, and remove tastes and odors from waters afflicted by them. Chlorination should be regarded as one of the processes accessory to filtration and used when necessary, just as aeration, coagulation, sedimentation, and other processes are used. Chlorination is also useful in emergencies.

When filters were first built emphasis was laid on bacterial removal and rightly so. But today water-borne diseases are well under control and the emphasis is shifting from bacteriology back to chemistry, although the problems of *B. coli* and *B. welchii* remain to be solved. Two

problems are now receiving much attention,—tastes and odors, and the corrosion of pipes. Some tastes and odors are due to growths of algae and other microscopic organisms. Sanitarians have learned that these can be controlled by filtration, by the use of copper sulphate, and by the use of liquid chlorin in slight excess. The recent growth of Synura in the water supply of New York City led to an investigation in the use of the excess chlorin method which contributed an important idea on this subject. But tastes and odors are sometimes due to other causes, to oils, to various mineral substances discharged into lakes and streams by manufacturing establishments. The use of chlorin may emphasize these tastes, and such expressions as the "iodoform taste" are becoming common. Chlorin itself may give an odor, but the secondary odors, due to the action of chlorin on other substances, organic, or inorganic, are more common. There are also odors of decomposition, and sometimes it is hard to distinguish these from the "chemical odors." Experience seems to indicate that slow sand filters are more efficacious in removing odors than mechanical filters. The longer contact with the biological slime found on the finer sand grains of slow sand filters appears to remove the odoriferous substances better than the short contact with the chemically formed film on the coarser sand grains of mechanical filters. Corroboration of this is found in the fact that the reduction of free ammonia by slow sand filters is greater than by mechanical filters.

From a purely scientific standpoint interest in water filtration is now centered around the phenomena of coagulation. The old and simple idea that when aluminum sulphate was added to water it was all changed to hydrate and removed by filtration appears to be unsound. Aluminum does go through filters and the corrosiveness of the filtered water and even the bacteriological efficiency of the filter are affected thereby. Waters differ greatly in their action upon alum, and the newer methods of physical chemistry, such as the determination of the hydrogen ion concentration and the study of colloids, are being employed to give, if possible, an answer to the many problems involved. The torch of research has been temporarily handed over by the bacteriologist to the sanitary chemist and in his hands it is now burning brightly.

Since 1914 the United States Treasury Standard for the qual-

ity for drinking water used by travellers on interstate carriers has been employed. In spite of its frequent misuse its influence has been for good. It clearly needs revision, however, to adapt it to more general use, and recently the United States Public Health Service appointed a committee to consider the matter. This investigation, only just begun, will last for perhaps two years. It is an advance in the subject which warrants attention, as the whole subject of water analysis is involved.

On the whole, it may be said that the art of water purification is in a healthful state of mature growth, with vigorous strivings toward perfection.

### Sewage Disposal

The latest development in the field of sewage treatment is the activated sludge process, a process of intensified biological action brought about by blowing compressed air into a tank of sewage after a part of the sludge previously separated from an earlier sewage flow has been added to it. It is a sort of hydraulic filtration. In intermittent sand filtration the sewage is brought in contact with sludge which has settled on and in the sand bed; in hydraulic filtration the sludge is blown or stirred through the sewage, and the same contact secured. Air is necessary in both cases. There seems to be no doubt as to the biological character of the process of purification, and organisms higher than bacteria are involved in both processes. The biological success of this process has been demonstrated, although the oil and trade wastes found in sewage sometimes injure the results. The problem of disposing of the vast quantities of the very liquid sludge produced by this process is still unsolved. If the sanguine hopes of those who think the sludge can be used profitably as a fertilizer are realized, the process will revolutionize present methods; if the same old difficulties of degreasing and dewatering the sludge cannot be solved so as to be a commercial success, the new process will take its place merely as one more method of disposal useful under certain conditions. Fortunately, the whole subject is under active investigation by sanitary engineers and soon there will be quite a number of full sized plants in operation, whereas at present there are only a few.

The subject of stream pollution does not appear to be getting the attention which it deserves. During the war governmental authorities relaxed

somewhat the severity of their control and, as a result, many streams are getting worse. Pollution control is always difficult to administer. It is a matter which does not necessarily affect health and therefore ought not to be exclusively controlled by health authorities. This, coupled with the fact that many stream pollution problems are of an interstate character, makes the problem of administration difficult. It certainly needs thoughtful study by a federal commission of some kind composed of men who represent manufacturing, law, engineering, fisheries, and health.

One fact which will have to be reckoned with in the future is the increase in the use of oil. Sewage contains more mineral oil than it did before the days of the automobile and the oil burning engine. Streams and harbors are more subject to oil pollution than formerly. In some places, especially along the Atlantic seaboard, this matter has been serious enough to warrant its being brought to the attention of congress.

There are many unsolved scientific problems in stream pollution, both biological and chemical. It must be admitted with regret and even with chagrin that the protection of streams against pollution has made no recent advance.

There have been no important advances in refuse disposal during recent years either in the art or administration. Perhaps the most notable event has been the publication of an excellent book on the subject by Messrs. Hering and Greeley. If there is any branch of sanitation in need of a thorough-going scientific investigation it is this one. Unfortunately, it is a subject which does not lend itself to small scale experiment. Studies to be of value must be made on a plant of considerable size and continued long enough to cover changing seasonal conditions. Some day these necessary experiments will be made. The federal government could well afford to pay for such studies even should the cost run up to a quarter or a half a million dollars, because the problem is one of importance in all cities and involves the conservation of substances which have a high money value, notably food, fertilizer, and grease, and because faulty methods of refuse collection and disposal affect the health and comfort of the people. Refuse disposal is one of these elements of municipal administration which emphatically needs a proper blending of sanitary science, law, and economics.

Mosquito control has had its ups and downs in recent years, but on the whole, notable progress has been made in the application of simple principles which are becoming widely recognized. A few new ideas have come to the front, but the greatest advance seems to be a better adaptation of methods to local conditions, a better conception of the proper balance between the expenditure of money for hydraulic measures that will bring permanent relief, i. e. drainage in its various forms—and palliative measures, such as the use of oils and insecticides, and top minnows, which, while usually necessary to some extent, require considerable expense for their continuance. Knowledge as to the habits of different species and varieties of mosquitoes has also increased. It has been learned, for example, that, whereas in our southern states the *Anopheles* mosquito can be controlled by measures which cover narrow strips of territory, in Porto Rico it is necessary to extend the work over much wider areas in order to get the desired protection from the variety of *Anopheles* found there. It has been learned that in making a popular appeal the term "mosquito control" is a better one than "malaria control." It is being recognized that mosquito control is going to become more and more a matter of engineering. In this as in many other activities one should follow the rule, first learn how to do it and then how to do it cheaply and efficiently.

### Plumbing

Just now there is a renewed interest in the subject of plumbing. Several states and many cities are considering revisions of their codes. The shortage of dwelling houses led Secretary Hoover to appoint a Building Code Committee to study the present legal requirements with a view to simplifying construction and reducing costs of small dwellings as far as this can be done with safety. A tentative report of this committee has been made, but not yet published. As the plumbing code presented peculiar problems, a special sub-committee on plumbing was appointed by Secretary Hoover. Under its direction experimental work has been carried on for several months by the Bureau of Standards, and as a result there should be a better understanding of plumbing requirements. It will soon be possible to set up a model set of regulations which can be safely followed for buildings of a given size throughout the country, making some

necessary variations for climatic and certain local conditions. It is possible to have simple plumbing layouts in dwellings of one or two stories, but plumbing installations should be so designed as to give a reasonable factor of safety against the escape of drain air, and so constructed that the inaccessible parts of the drainage system will be as permanent as the rest of the building. In buildings of three or more stories the hydraulic and pneumatic conditions are such as to require more elaborate systems of piping in order to secure reasonable protection. Although the air from sewers seldom, if ever, causes specific disease, it is insanitary and indecent to allow it to escape into rooms occupied by human beings. If men want simple plumbing, they must build simple buildings.

For other reasons than those connected with plumbing the small detached house is preferable to any sort of multiple house for the wage earner. It is true that there are economies in the multiple house and that if people insist on living in large cities there are bound to be multiple houses. But tenement life is a smothered and starved life, physically, mentally and morally. For this reason health workers should strongly support the decentralization movement and the zoning idea which are making such splendid progress throughout the country. The city planners of today are men of vision. They do not limit their thoughts to cities—they are planning for districts and large areas. There is further need to build up the rural districts, to improve sanitation on the farm, to give the farmer all the comforts and conveniences that the industrial worker in the city has. The future of our country is in grave danger if our rural regions become deserted and our cities become packed.

All of the subjects mentioned have to do with public health and especially with sanitary engineering. Although the work is constantly becoming greater, the number of students entering this field of activity has not been increasing in recent years as it should increase. The war and the trend of business conditions seem to have turned the minds of young men towards occupations which bring fees and profits rather than salaries. The political factor has also had its influence. Conditions are changing, however, and sanitary engineering will be an attractive occupation for the young men of tomorrow.

As we study public health administration and education, we see things

more clearly than we did a few years ago; we see that it is well for health officers to have a fundamental medical training, and we see that it is well for sanitary engineers to have a fundamental engineering training. These ideas are reflected in the changes recently made in Harvard University. A new School of Public Health of Harvard University and the Massachusetts Institute of Technology will henceforth require a medical degree as a prerequisite for the degree of Doctor of Public Health; while in the Engineering School the degree of Master of Science in Sanitary Engineering will be given only to students who have previously taken a bachelor's degree in Civil (or Sanitary) Engineering. These changes merely recognize the fact that health administration has two sides—a human side and an environmental side. Engineers and doctors must work together, but each must recognize the other's qualifications and limitations.

The reason why young men should study sanitary engineering and go into the public service is not for their own gain, although it will pay them.

but because our country needs them. Health officers know that public service is a personal sacrifice. They put in more than they get. They always will and they always ought to. Service is always sacrifice. Our country never lacks for patriotic service in times of war. Young men should do as much for their country in peace time as they would do in war time. No one can do more to influence our best young men to take up public health as a life career than men who are already in it. There is a disposition on the part of many public health officers, city engineers, and others to complain of their troubles. No one can blame them, and yet, after all, is there not a joy in seeing death-rates go down; in seeing preventable diseases disappear; in seeing streets cleaner and houses better; in seeing cheeks rosier, muscles firmer, and backs straighter? Is there not a satisfaction, greater than that which comes from large money earnings, in feeling that one has had his little part in making the world a better place in which to live? And if this is so, why not tell it to the young men?

and tube of peptone solution and these are examined after eight hours. When abundant spirilla are found on the surface of the peptone solution, these are tested with a highly specific anticholera serum. These tests can be completed in from twenty-four to thirty-six hours and are almost certain to detect carriers and cases. Plate cultures, isolation of the spirilla, and agglutination tests may be used for verification.

*Bubonic plague:* Some bubo material, blood, or sputum is cultured on nutrient agar, some is planted in broth and some is rubbed on the shaved skin of a guinea pig. Other material is spread on slides, stained, and examined. After twenty-four or thirty-six hours the cultures are examined. If after investigation the cultures are still suspicious, they are fished and examined. If colonies are suspicious they are inoculated in guinea pigs and rubbed on the hair free skin. The results are known in about forty-eight hours and are very reliable.

At the first meeting of the Federal Board of Maternity and Infant Hygiene, held recently, the plans of all the states which have to date presented final plans for the use of the funds available under the Maternity Act were approved for the year ending June 30, 1922. This includes 23 of the 41 states which have officially accepted the Act. Miss Grace Abbott, Chief of the Children's Bureau of the U. S. Department of Labor, was elected chairman of the Board. The members of the Board are Miss Abbott, Dr. Hugh S. Cumming, Surgeon-General of the U. S. Public Health Service, and Dr. John J. Tigert, U. S. Commissioner of Education. The States whose plans have been presented and approved are: Alabama, Arizona, Arkansas, Connecticut, Delaware, Florida, Georgia, Idaho, Indiana, Kansas, Kentucky, Mississippi, Missouri, Nebraska, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, Montana, Virginia, and Wyoming.

Dr. William K. West of Trimountain, Mich., has been appointed consulting surgeon for institutional work in the Upper Peninsula, according to an announcement by Dr. R. M. Olin, state health commissioner. Dr. West is surgeon for one of the mining companies of the copper country. The surgical work at the branch prison at Marquette will come under his supervision.

## Tests for Import Diseases

QUARANTINE for import diseases at ports involves the problem of inspecting for disease and yet not holding the passengers or cargo for an undue length of time while so doing. If an undetected case of typhus fever, bubonic plague, or cholera is passed into the country great expense is caused the health authorities and public excitement created; on the other hand if the thousands of passengers are detained they are greatly inconvenienced, steamship companies have their expenses greatly increased, and commerce is seriously affected.

William H. Park, M.D., Director of Laboratories, New York City Health Department, describes in the *American Journal of Public Health*, the tests for these specific diseases which a highly trained diagnostic laboratory should be able to make without great loss of time. Such a laboratory should be equipped to the last detail with slides, swabs, tubes, specific agglutinating sera and media for carrying out the work.

The laboratory force should have trained technicians one at least of whom should have some medical training and be competent to make inspections with the medical officers and

help decide what cases are suitable for laboratory help. Besides keeping from the country the usual import diseases mentioned above, such a diagnostic laboratory might be asked to make examinations for leprosy, tuberculosis, and venereal diseases.

The tests which can be quickly and reliably made by a trained force adequately equipped are as follows:

*Typhus fever:* Between the third and fifth day the blood of up to 50 per cent of typhus fever patients will agglutinate in fairly high dilutions the proteus bacillus isolated by Felix and Weil. During the next few days the great majority of the remainder will react. Few, if any, diseases other than typhus fever give this reaction. A preliminary slide agglutination can be done on the vessel or a report issued within two hours if the blood is sent to the laboratory.

*Cholera:* Cases not having diarrhea are given a dose of salts. After the salts have operated a sterile swab is passed into the rectum and withdrawn. It is dropped into a tube of peptone solution. When all the crew and suspected passengers have been cultured, the tubes are incubated for eight hours. A loopful of the surface growth is inoculated into a sec-

# The Mental Hygiene Bureau of Connecticut\*

## The Work of a New Bureau and Its Comprehensive Program for Expansion

BY WILLIAM B. TERHUNE, M.D., DIRECTOR, BUREAU OF MENTAL HYGIENE, CONNECTICUT DEPARTMENT OF HEALTH, HARTFORD, CONN.

AT THE present time the term mental hygiene is loosely employed although in recent years books have been devoted to explaining its principles, while daring authors have ventured to define it in a terse statement. There are those who treat the subject in a philosophical manner, holding that the general application of its principles would smooth life's pathways; others consider it as a branch of science and, unfortunately, there are many who deem it merely an euphonious phrase. It is impossible to meet on common ground without explaining at the outset a conception of mental hygiene, not that it has the merit of originality, but that the basis for this presentation may be clearly understood.

Mental hygiene is a lay expression which is practically synonymous with the medical term psychiatry and it was originated for the purpose of offsetting and neutralizing the socially offensive term insanity. It has been said that the field of mental hygiene was greater than that of psychiatry, inasmuch as the former not only embraced the individual, but also the legal and social factors involved. This argument is not valid. Psychiatry necessarily considers the same factors, realizing that not only do individual physical maladjustments play a part in disease, but that environmental and social factors are similarly of great importance. Therefore, since we consider insanity and other departures from normal mentality as forms of disease, and psychiatry as the science of the study and treatment of such disease, mental hygiene is basically a medical undertaking, interested likewise in the study, prevention, and proper treatment of mental disorders, with this difference perhaps; medical ethics forbid the exploitation of psychiatry while mental hygiene, having originated outside of the medical profession, has larger opportunities of an educational nature. This conception of mental hygiene, namely, that it is primarily medical in nature, has been the basis of mental hygiene work in Connecticut during the past

three years and this explains why, during the past few months, a bureau of mental hygiene has been instituted in the Connecticut Department of Health, as it is the logical place for such a bureau from the functional standpoint. The progressions and regressions of mental medicine from the time of the early Egyptians up to the present period demonstrate that the treatment of the mentally aberrated has advanced only during those periods of the world's history when such patients received medical attention.

The study of evolution of the treatment of disease is most interesting. It would seem as if the pendulum of medical procedure constantly oscillates between the ultra-conservative and ultra-radical points in medicine, yet fortunately there is a progressive tendency towards stabilization. This is not only true in the treatment of individual disease, but there are apparently trends of public and medical opinion which likewise change from time to time and affect the entire intellectual world. For example, during the past twenty years there have been definite changes of opinion in the medical world in regard to the proper treatment of, let us say, tuberculosis. At first, the tendency was to leave the patients in the community, later a great effort was made to hospitalize them and now they are first hospitalized for study and treatment as well as educated as to how to care for themselves and later, with some exceptions, are returned to the community.

### A Community Responsibility

The colonial history of the care of the insane shows that such patients were at first cared for in the community. The first record of public relief for a mental patient in Connecticut is found in the records of the colony of New Haven for 1645, when a patient is stated to have been partially relieved in her home. In 1648, an additional record is made that the same person had been cared for in the home of the marshal, who asked to be relieved of her care. Until the year 1824, when the Hartford Retreat was founded by the State Medical Society, mental patients in Connecticut

received little medical attention. Capen says it is hardly necessary perhaps to imagine how these unfortunates were cared for, "but it may be mentioned in passing that in a memorial presented to the Assembly in 1786, Mary Weed of Stratford stated that for twenty years her husband had been so insane as to be kept 'chained.'" The insane poor, being classed as paupers, were annually sold at auction to those who were willing to assume the care of such confessedly undesirable persons for a money consideration.

Sixty years ago, the first state hospital was opened at Middletown and forty years later the second at Norwich and since these hospitals were erected, the hospitalization of mental patients has been the most efficient method of caring for them. And so the treatment of mental disease has passed through definite phases comparable to other diseases, such as tuberculosis, namely; a phase of inefficient community care, followed by a phase of hospitalization and the next step in the treatment of mental disease is a combination of these two, that is, hospitalization in the incipency of the disease for a period of intense study and re-education, followed, in a large number of instances, by return of the patients to the community under close psychiatric supervision.

In 1814, the Connecticut Medical Society, with the help of the General Association of the Congregational Clergy, secured information concerning the extent of insanity in Connecticut, they found "146 persons who, in different degrees, are deprived of reason." In 1821, one hundred years ago, a committee appointed by the medical society reported that there were at least one thousand mentally deranged individuals within the state. On both occasions, some citizens denied the existence of such a large number. This is cited realizing that the present crude estimates may be similarly criticised. The number of mentally ill patients among the citizens of Connecticut is not known. At the present time most of the state mental hospitals in this section of the country are filled to capac-

\*Read before the New England Health Institute, Hartford, Conn., May 2, 1922.

ity and in Connecticut this is particularly true. The Connecticut State Hospital at Middletown has 2,698 patients, six hundred more than they have facilities to care for. The Norwich State Hospital has one thousand six hundred, and although it is a new institution, it is already crowded. The Mansfield Training School has six hundred patients, they have a waiting list of approximately two hundred.

The percentage of increase of psychotic patients in state hospitals was enormous in the eight years from 1910 to 1918, and this increase has certainly continued since that time. In the eight years mentioned, the increase in Connecticut was 21 per cent against a population increase of 14 per cent. Bearing this in mind, what might we expect in the future? It is impossible to make a definite statement in regard to this, but according to population charts estimating the rate of population increase, the population of Connecticut will probably be doubled in another twenty years, which would lead us to suppose that the institutional population in this state would be more than doubled in that period of time. In other words, if there are over four thousand two hundred patients in our state hospitals for psychotic patients at this time and the ratio of institutional increase over population increase is as three is to two, in twenty years from now, we may expect ten thousand in our state hospitals. The above estimate is only for such patients as are admitted to our state hospitals since we have no way of computing the number of patients treated in private hospitals nor those who, at the present time, receive no treatment whatsoever. The number of mentally deficient individuals in the state are not included in the estimate, but assuming that Goddard's estimate that one out of every two hundred and fifty of population is feeble-minded, is correct, in twenty years with an estimated total population of over two million, there would be from eight thousand to ten thousand feeble-minded individuals in this state. It should be remembered that these figures are only surmises and are of no use except for comparison and illustration. But manifestly it will not be possible to treat such a large number of mentally aberrated patients for long periods of time in state hospitals, it is therefore necessary to take the next step in psychiatry and materially increase the number of patients on parole and also to provide early treatment for the incipient cases in order that their pe-

riod of hospitalization may be as brief as possible.

The need for a state agency to coordinate and supervise mental health work was recognized some years ago in many parts of the country and resulted in the establishment of such agencies, some of which have been given considerable authority and a wide scope for their activities. These agencies have been, as a rule, independent departments of the state government and such a form of organization is the most satisfactory one. The functions of such departments vary in different states, but broadly speaking, they outline the policy of the state in treating mental disease, supervise the state and private hospitals and coordinate the various activities of the state hospital. Such a commission as this does not exist in Connecticut. The Mental Hygiene Bureau was instituted in the Department of Health for the purpose of meeting this need, for, as before stated, the logical place from a functional viewpoint, for such a bureau was in that department which had under its supervision the health of the people of the state. Dr. Lewellys F. Barker, Professor of Clinical Medicine, Johns Hopkins University, made the following statement last year: "That schools of hygiene and the public health services must soon fall into line and consider mental hygiene seriously is obvious. The objection sometimes made that the practical problems are too vague, not sufficiently concrete, to justify attack by public health officials is no longer valid. In no direction, probably, could money and energy be more profitably spent during the period just ahead than in the support of a widely organized campaign for mental hygiene." Similar statements have been made by Dr. Thomas H. Haines of the National Committee of Mental Hygiene and by Dr. C. M. Hincks, the latter in a paper entitled, "Mental Hygiene and Departments of Health" published in the *American Journal of Public Health* in 1919. In 1917, the United States Public Health Service published an official report showing the need of mental hygiene in public health work and outlining such a division for the Public Health Service. In Connecticut, the Bureau of Mental Hygiene was instituted on paper, that is, without any funds, in 1919 and the last legislature appropriated the sum of \$3,000 for this work. Even with this pitifully small sum, the Bureau has been able to function and when it receives a larger appropriation, there

is no doubt that it can be of great service to the people of this state.

Three separate developmental steps have been considered in outlining a mental health program. The last might be called the "ultimate program," the one before that the "next development" and the one before that, the "present undertaking." Broadly speaking, the ultimate program should be one of general supervision and coordination of departments and agencies caring for mental patients. When the time is ripe for such a program, it is hoped that the work will be carried on by an independent department of the state government.

The plan submitted to the Commissioner of Health by the Director of the Bureau of Mental Hygiene formulates its purposes of undertaking as:

- (1) To discover the numerous mentally sick and defective individuals in this state who receive no treatment now and provide treatment for them insofar as possible.
- (2) To discover and record cases of mental disease and defect in Connecticut, to ascertain the factors responsible for these conditions, and with this information in hand to render a report to the state authorities recommending the most logical method of handling these problems.
- (3) To study the relation of mental disorders to social inadequacy, with special attention to delinquency, dependency, health, industry, and education.
- (4) To conduct a campaign of public health education relative to mental disorders—to combat mental disease with every measure known to medical and sociological science—in other words, to make war on mental disorders in Connecticut as vigorously as one would fight plague, tuberculosis, and cancer.

The program submitted included (1) a mobile psychiatric clinic. A mobile psychiatric clinic could practically cover the entire state, operated regularly in the centers of population and visiting the outlying districts when special problems arose. This clinic would diagnose, treat and recommend proper treatment for mentally ill and mentally defective individuals.

(2) A survey should be made not only of mental disorders, but rather of social inadequacy in Connecticut. The purpose of this survey would be to determine the existence of and register all mentally diseased and defective individuals in this state. To trace as closely as possible the relationship which mental disease and mental deficiency bear to other problems, and to examine and appraise the value of the different efforts, large and small, official and unofficial which the community is putting forth in its efforts to deal with them.

With such information in hand, a comprehensive program for the treatment of mental disease and defect could be formulated.

(3) An earnest effort should be made to prevent, or at least to curtail, the occurrence of syphilitic psychoses.

Approximately fifteen per cent of insanity is the result of syphilis, and here, when considering the paretics, we have a disease so formidable that the mortality rate practically coincides with the morbidity rate. It has been estimated that at least five per cent of the known syphilitics develop paresis. In New York several years ago, Wassermann serum tests were made on the members of 463 families, from each of which a paretic had been taken. Twenty-five per cent of the members of these families had syphilis and practically none of them suspected it.

The bureau of mental hygiene can, by cooperation with the laboratory and genito-urinary division of the Department of Health, watch the known syphilitics in the state for signs of central nervous system lues. It is known that the most efficient method of preventing involvement of the nervous system is early diagnosis and prolonged treatment. Patients who have been infected should be kept under medical observation for many years.

The preventive work in neurosyphilis as outlined here is not very difficult to put into practice, it is being done at least in one state at the present time. The procedure is comparatively simple; the laboratory reports all positive seriological findings to the commissioner of health who sends the physician reporting the case a card asking the physician if he will not allow the case to be reported by name and address, if this was not given at the time when the specimen was sent in. Every year the doctor is sent a card requesting information regarding the progress of the condition of the patient, what treatment has been given and if there is any evidence of central nervous system involvement. This card also brings to the physician's memory the fact that when cerebro-spinal lues occurs, the spinal fluid is usually positive in approximately the fourth year after the original infection. By discovering these early cases of cerebro-spinal involvement and treating them, it is possible that we may be able to reduce the occurrence of many luetic nervous system syndromes.

(4) The power now delegated to other departments of the state government in regard to the inspection and licensing of private hospitals, inspection of state hospitals and all other matters of such a supervisory mental health nature should be transferred to the Bureau of Mental Hygiene.

Considerable space has been taken to outline the next development of the work of the Mental Hygiene Bureau. The present undertaking of this bureau began on October 1, 1921. Previously, in this paper, it has been stated that the proper method of caring for mental patients was by a combination of hospital and community treatment. The belief in this principle has led the bureau to undertake a demonstration, first of the value of intense psychiatric supervision of patients paroled from state hospitals and, secondly, of the treatment of selected patients in the community without having recourse to hospitalization. Mental patients are in hospitals for one of four reasons, namely: (1) because they can be helped or cured by such treatment; (2) because they are a menace to the community; (3) because they have suicidal tendencies, or (4) because of economic conditions. Let us consider these reasons separately. A time may arrive in the course of hospital treatment of mental disease when the patient is apparently no longer benefited by hospital treatment, such patients, under intensive supervision, may frequently be returned to the community. There are again patients who, after a period of hospital treatment, may even improve faster in the community than in the hospital. It is with this first group that we are most interested, for naturally, those patients belonging to the second and third groups cannot and should not be treated in the community. We have been able to be of some assistance to those patients of the fourth group, namely, those patients who are in a hospital because of economic or family circumstances.

The procedure of this intensive parole work is as follows: The work is conducted in close cooperation with the state hospitals. The psychiatric worker periodically visits the hospital and the clinical director gives her a list of patients whom the ward physicians consider might possibly be paroled under very careful supervision. The clinical director, at this time, discusses the cases fully with the social worker. Next, the records are studied to learn exactly what the circumstances were which led to the patient's psychosis and to give the worker a picture of the social and economic setting in which the illness occurred. The names and addresses of the relatives and interested friends are obtained and any little facts about them which indicate whether or not they may prove cooperative. Each patient is interviewed and is encour-

aged to talk of his plans for the future when he shall once more be a part of the outside community. This first interview, obviously, is a golden opportunity to gain the patient's confidence.

When the worker returns from her trip to the hospital, she makes a thorough social investigation of the home situation in order to discover factors which may have an influence on the patient after his parole. If the home offers any possibilities, an effort is always made to have the patient live there. This is the time for educating the patient's family to a better understanding of his illness and explaining to them in detail what they can do to facilitate his improvement. It is sometimes necessary to make repeated visits in order to arrive at the desired state of understanding and cooperation before the patient is paroled. The consultations with the family are continued after the patient comes home and an effort is made to assist as each definite difficulty arises. When, as is sometimes the case, the home conditions are found altogether unsuitable, or perhaps the patient has no home, it is the social worker's job to find a desirable place for him to live. When the patient first leaves the hospital, it is better for him to be in as simple an environment as possible so that the transition from hospital to extra-mural conditions may require little effort on his part. This fact is always kept in mind by the worker in order to avoid too sudden or complete a change from the simplified hospital surroundings to the more complex world outside.

As soon as the pre-parole investigation is completed, the hospital is notified and if it has been possible to make suitable arrangements, the patient is now paroled. Immediately upon his arrival, the worker calls and renews the contact made at the hospital. In most cases, suitable work is obtained for the patient. His condition is always explained to the employer and close cooperation established between him and the worker. As the patient's welfare is the first consideration, great stress is laid on the kind of work and desirability of the surroundings rather than on the financial remuneration. It is interesting to note in this connection that of the patients now on parole under our supervision, about 50 per cent are gainfully employed. A number of the remainder are housewives who are doing successfully their domestic work and caring for their children; while the others who are not yet ready for

the more taxing and regular work outside are being interested in occupational therapy in their own homes. In many of our paroled cases, there is a great need for occupational therapy. Whenever possible, we try to continue this along the lines followed by the hospital. This has proved to be of such wonderful assistance for rehabilitating the patient and is so greatly appreciated by both the patient and his family that we have come to feel that one of the greatest necessities in our paroled cases is to continue at home the occupational therapy which has usually been so successfully begun by the hospital.

During the period of parole, periodic psychiatric examinations are made by the medical director in each case. These are in addition to daily conferences between the worker and physician when the immediate needs are discussed. However, after each psychiatric examination there is a thorough and careful study made of the case with a review of the progress of the patient and a checking up of all treatment. At this time, the physician outlines the treatment for the future. The task of finding a way to execute this program is the function of the social worker. Perhaps exactly what is done can be explained more clearly by summaries of some records of patients who are now on parole under our supervision.

I—is a female patient, 46 years of age, born in Ireland. She went to school until 15 years and as an adult was always considered intelligent and well informed. She came to the United States when 19 years of age and was employed as a factory worker until 25 years of age when she married and later gave birth to seven children. Six months prior to admission to the hospital, her oldest son died after ten days illness during which time patient nursed him. She never seemed to recover from the depression caused by his death and her condition became progressively worse. On admission to the hospital, the diagnosis was involuntal melancholia. After five months of hospital treatment, she began to gradually improve and three months later was paroled into the custody of her husband. The patient had been at home scarcely four months when her husband committed suicide by cutting his throat. Patient again became agitated and depressed and was returned to the hospital for further treatment. It was three months after that she was referred to this bureau for the consideration of parole. The patient's

sister was visited. The surroundings were found to be good, the home attractively furnished, neat and clean. The family was large and the sister was caring for the patient's three daughters. (The patient's three sons were with a brother-in-law in the same city.) The priest (patient is a Roman Catholic with normal religious interests) was interviewed and his cooperation was easily secured before the patient left the hospital. After arriving home, she got along well, but before long she began to be dissatisfied with her sister. The physician recommended that she be installed in a home of her own with all her children with her. To do this required money and there was none. The Widows' Pension was tried but, although the patient had been married and all her children were born in this Connecticut city, she was ineligible because her husband was not a citizen. In the meantime, an effort had been made to secure employment for the two who were beyond school age. After several attempts, both were finally placed and are still working at the same jobs. Of course, the wages of these two were wholly inadequate for a family of seven and, as the patient and her children were already settled in a sunny five room apartment (this was necessary before an application for the Widows Pension could be filed) it was necessary that other income be secured and that quickly. Despite her efforts to remain cheerful, patient was becoming depressed. Several social agencies were called upon. From one, a daily ration of two quarts of milk was secured; another promised to pay half of the rent and in addition furnish some groceries; while a third undertook to keep the four children at school supplied with shoes and clothing. As one after another of these promises were obtained, the patient became less worried and finally was again cheerful and happy. Then her teeth were found to be bad and the physician ordered new teeth at once. Here it was again necessary to secure the cooperation of a charitable agency who paid the dentist and whom the patient is repaying at the rate of \$1 a week. All this was accomplished several months ago and of late the supervision has needed to consist only of friendly visits, an occasional ride in an automobile, and little encouraging lifts as when our visitor secured a dainty white dress for the six year old daughter who had been chosen to take part in a religious Easter service. Next month, the oldest boy will get

his working papers and that patient is looking confidently into the future to the time when her children will be working and they will be independent of outside help.

II—is a female patient 35 years of age who is diagnosed as "mental deficiency with psychotic episodes." She was born in Connecticut, her mother was queer and immoral and her father was considered feeble-minded. A maternal uncle is mentally aberrated. Her parents separated when she was five years old and five years after she was sent to an industrial school where she remained until she was 21 years old. After leaving the school, she led a grossly immoral life during which time she had a number of miscarriages and one child who died. She was arrested, charged with lascivious carriage and a year later (February, 1921) she drank carbolic acid in an attempt at suicide. This, according to patient's statement, was because the man with whom she was then living, refused to marry her. It apparently accomplished the desired result as in July of the same year, she was married. It was at the time of her attempt at suicide that she became known to the Mental Hygiene Society and she was under their supervision until in October she became excited, threatened suicide and was finally committed to a state hospital. While there, she adapted herself to her environment, seemed happy and contented. She claimed that all her queer actions were due to the fact that she feared her husband would leave her. After five months of hospital care, she was referred to us for consideration of parole. It was found that her husband had sold the furniture and was making his home with an aunt who opposed patient's parole. However, her husband was so anxious to bring her home, that when he came to us and said he had secured a desirable boarding place with friends (which statement we investigated and found to be true), we consented to try the patient. As soon as she was paroled, the physician saw her and recommended that a job be found for her and that she be encouraged to continue the crochet work she did at the hospital. Through the cooperation of relatives, a job was finally found for the husband at a local factory. The patient was encouraged to crochet yokes and as many of these as she made were sold for her by our worker. Finally, the patient decided she was not making enough money this way, so a job was secured for her at the same factory

where her husband was employed. The cooperation of her church was also secured and the deaconesses interested in her. Both patient and her husband worked until quite recently when she was obliged to lay off temporarily because of digestive trouble. Her husband, however, is still employed at the same job and patient is again occupied crocheting yokes.

III—is a negro, an ex-soldier, 29 years of age with a diagnosis of dementia praecox. For several years, before his commitment to a state hospital in May, 1919, he had been the "unsolvable problem" of several local agencies. In December, 1921, he was referred to us for consideration of parole. He was seen at the hospital, the physicians were conferred with, extracts made from the records, local agencies and all near relatives were interviewed. It was found that patient was an orphan with an aunt acting as conservator for his government compensation of which he received eighty dollars a month. This aunt lived in a tiny apartment and was not able to take the patient with her. The cooperation of the colored rector and of a colored physician was secured and a large number of possible boarding homes inspected without anything desirable. Finally another aunt was prevailed upon to try boarding the patient. Here he was to have an airy room to himself (he was suspected of having tuberculosis by a public health doctor), and suitable food. The patient was pleased with this arrangement and paroled under our supervision. The cooperation of his relatives was obtained in providing recreation for him and before work was secured it was felt that he should receive treatment for an old venereal infection. This was arranged for through a local hospital and he had reported regularly for treatment. After his last psychiatric examination, the physician recommended outdoor work and the visitor is now interviewing nurserymen, florists, etc., with the object of obtaining work in desirable surroundings.

IV—is a male patient, single, 48 years of age with a diagnosis of "alcoholic psychosis—chronic hallucinosis." He had been a patient at a state hospital for over ten years when in November 1921 he was referred to us for consideration and parole. The hospital record was gone over carefully, his special abilities and disabilities noted with the object of utilizing the former when he returned to the community. The home

investigation revealed the fact that his sister-in-law, who has a large family of her own, could take him to live with her if work was provided for him. For a while after his parole, the patient continued to hear voices, but does so no longer, his insight and judgment are defective, and although he is not well, he has been doing nicely. The real problem has been keeping the patient at work in a city where the unemployment situation is particularly acute. This has been done more or less successfully by eliciting the cooperation of every person or agency that could possibly be of use in an employment problem. In this way, a job of a few weeks duration has been secured and when this ended, another found. It has been necessary to do this a number of times, but with the exception of several days, or perhaps a week between jobs, the patient has been kept constantly occupied. For the past three weeks he has been working steadily, and as the factories are picking up, we hope this will continue.

Of the 66 cases so far referred to us by the state hospitals, 29 or 44 per cent have been found suitable for parole. Of these it has been necessary at some time to return 7 or 23 per cent of those actually paroled, to the hospital for further treatment. We have at present 22 cases on parole and pre-parole investigations are completed in a number of other cases whom we expect to have paroled in the near future. Of the patients paroled, 14 have been diagnosed as dementia praecox, 3 as manic depres-

sive, 1 as psychosis with other somatic disease, 2 as mental deficiency with psychosis, 1 exhaustive psychosis following childbirth, 1 as psychoneurosis, hysterical type, 1 alcoholic psychosis, chronic hallucinosis, 2 as involuntional melancholia, 1 as psychosis with cerebral arteriosclerosis, 3 were not diagnosed at the hospital. Of those whom it has been necessary to return for further treatment, 4 were diagnosed dementia praecox, 2 manic depressive and 1 involuntional melancholia.

### Conclusion

The Connecticut Department of Health has instituted mental hygiene believing that under the circumstances such an undertaking was incumbent upon it if the department kept faith with the people of the State. We look upon it as a new development and both the Commissioner of Health and Director of the Bureau are, I believe, attacking the problem with an open mind. For too long mental disease has been the *bete noir* of humanity, and this, mankind's last spectre, must go!

A commission for child welfare established by a recent Peruvian Government decree is entrusted with the duty of protecting childhood in every possible way. Half of the 10 per cent tax on amusement tickets is appropriated for the work of the commissino which has already proposed converting the exposition work into playgrounds for children and holding a national child-welfare congress

### Mt. Sinai's Roof Garden for Children

Wide World Photos.

A roof garden to which children are not barred is located on the top of the new addition of Mt. Sinai Hospital, New York, which was built through popular subscription especially for child patients. Unlike most roof garden devotees, these patrons are not sun dodgers.

# Disinfector for Canadian Quarantine Service

## Construction and Use of a Disinfector and Power House for Maritime Service

BY B. EVAN PARRY, M.R.A.I.C., SUPERVISING ARCHITECT, FEDERAL DEPARTMENT OF HEALTH, OTTAWA, ONT., CANADA.

THE disinfecting and power house of a quarantine station offers in part an illumination upon the never ceasing activities which are carried on from day to day on our Canadian maritime coasts by the Federal Quarantine Service.

The significance of the term quarantine and the administrative scope of this function of government may be better understood by a brief historical survey covering the practice and principle which obtained in the past centuries and those of today.

It is recorded that the Duke of Lombardy in the year 1383 ordered that no persons should be allowed to enter his kingdom from any infected place under the penalty of the yoke. Other penalties mentioned are whipping, exile, torture, long service in the galleys, work among the sick in a pest hospital, and death.

In the year 1603 an act was passed in England for the relief and ordering of persons affected with plague, but did not contain any provision relating to maritime quarantine, merely dealing with the isolation of persons within England.

An interesting dispatch forwarded in the year 1839 to the late Chief Justice of the Mauritius emphasizes the gradual progress made in the science and practice of quarantine.

*Inter alia* this dispatch stated: that the Lords in Council of Great Britain have called upon the Superintendent General of Quarantine for his opinion upon the subject, who has stated that the quarantine laws having been established chiefly against the plague, a disease not to be dreaded excepting by the Mediterranean colonies; he does not conceive it necessary in any of the others to establish any quarantine department for the opening and airing articles of merchandise from the Levant similar to those established in this country. (England) and as to the other diseases to be apprehended the only quarantine arrangement he recommends against them is the appointment in every colony of a health officer and the principal army medical officer at the station with a moderate salary in addition to his pay, who shall be required to visit and report upon every vessel arriving previously to her being permitted to communicate with the shore, and who shall have under his superintendence a hulk

or unseaworthy man-of-war, or a detached spot on shore fenced in with proper sheds or buildings, so that in the event of a vessel arriving with disease on board, an opportunity might be afforded of separating or altogether removing the crew, with the view of cleansing and purifying the vessel, as well as the clothing and bedding of all persons on board.

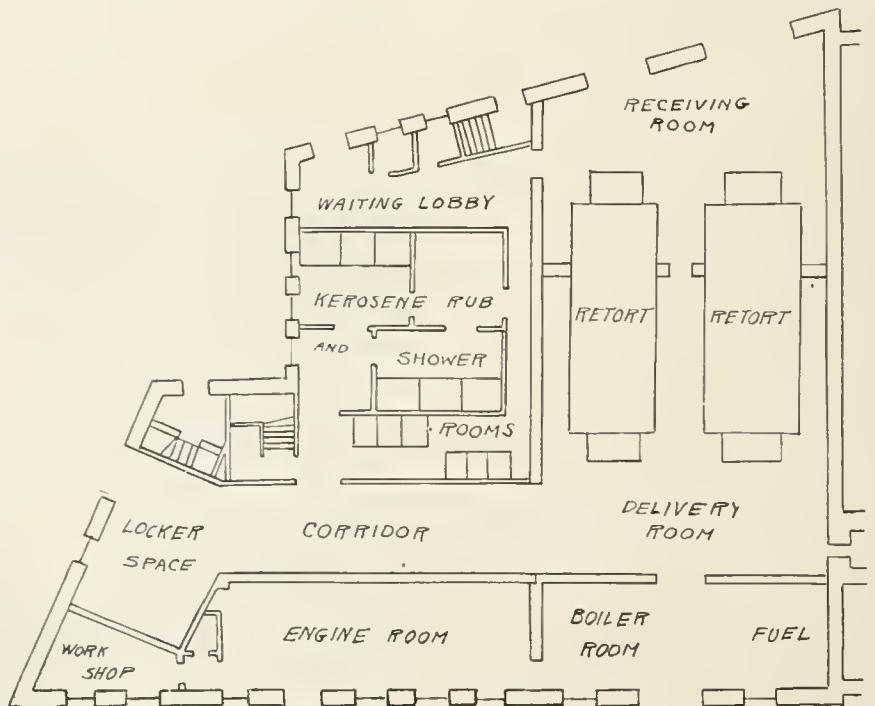

Although in the middle of the nineteenth century Great Britain freely admitted vessels which were found to be healthy on inspection, other countries retained the old system which considered it necessary to impose quarantine on vessels from England. It was, therefore, necessary to take steps towards a uniform system which could be adopted by all countries. With this object international conferences were held in Paris in 1857 and again in 1859, neither of which was in any way conclusive. The next was held in Constantinople in 1866, and at this conference some system was introduced into the practice of dealing with vessels, the measures to be taken being based on a foul bill of health indicating an infected

port of call and the sanitary history of the vessel during the voyage. This conference was noteworthy because for the first time important principles were recognized, *i.e.*:

(1) Restrictive measures recognized beforehand and satisfactorily carried out are much less prejudicial to commerce and to international relationships than the disturbance to industry and to commercial transactions which follow an outbreak of cholera.

(2) The nearer quarantine and other preventive measures are applied to the original source of the epidemic, the less burdensome are they, and the more can their efficacy be relied upon.

At the Vienna Conference in 1875 the majority of the countries adopted the English system of medical inspection and at the 1881 Washington Conference, international notification of infectious disease first became officially recognized. The convention signed by the delegates to the 1911 Paris Conference was responsible for the provisions relating to yellow fever based upon its verified transmission by mosquitoes and

First floor plan showing (1) receiving room, (2) waiting lobby, (3) kerosene rub and bath rooms, (4) disinfectors, (5) delivery room, and (6) locker space.

for bacteriological examination in the case of cholera. The rôle played by rats in the spread of plague has already been recognized in the Paris Conference of 1903.

Thus is fully exemplified the adoption of international hygiene to increased scientific knowledge and the inadequate measures of the past have become replaced by intelligent application of carefully verified facts, also that international cooperation is the most satisfactory method of dealing with infectious diseases which are liable to spread from country to country.

The Canadian Quarantine Regulations have been framed with the foregoing principles as a basis and among others the following closely pertain to the subject under review:

Every vessel shall be inspected immediately on arrival.

Every quarantine officer shall satisfy himself as to the presence or absence of infectious disease by the personal inspection of those on board or by the sworn statement of captain or surgeon in the form hereto appended, or by both.

Every vessel with infectious disease on board or coming from an infected port or country shall be liable to be detained at a quarantine station for disinfection or observation, together with its passengers, crew, pilot, luggage, and cargo.

To carry out these regulations, it is obvious that with others a disinfectant building embodying the various processes is of paramount importance to a quarantine station.

Therefore under the direction of Dr. John A. Amyot, C.M.G., Deputy Minister of Health, Canada, plans were prepared embracing not only precepts laid down for quarantine in the past, but also valuable experiences gained in the world war where disinfection and disinfestation both of personnel and clothing played a very great part in the comparatively low death rate of the troops from disease.

The building under review is located on the wharf of Partridge Island, St. John, N. B., which enables the passengers and luggage to be treated before dispersing to the various buildings allotted to them for hospitalization or detention purposes as may be necessary.

The practice observed when disinfecting detained passengers may be described as follows:

Passengers after leaving the ship proceed to the waiting room where they are provided with a metal disc, numbered, to hang around the neck, a locker correspondingly numbered, some cord, also a string net bag is provided for personal belongings, which bags are woven by the boat crew, and a tag similar to the other already provided.

Six persons are then admitted to the disrobing room, where they undress and place their underclothing, and such of their outer clothing as will not be injured by steam, in the locker. They tie their shoes and such other articles as would be injured by steam

in a bundle and attach the spare tag. All these are removed by the attendant to disinfector, using a hand truck.

After disrobing, the passengers are admitted to the bathroom where the process of shower, soaping, shower, soaping, shower, drying, then kerosene administered by spray takes place. This method may be slower than administering the soap by spray, but experience has proved that more attention can be given the individual and, therefore, the result is more effective. The passengers are then passed on to the pyjama or exit room, where the attendant distributes sterile pyjamas to each, after which they proceed upstairs to the waiting rooms where the kerosene is allowed to dry before putting on their clothes, the latter having been brought to them from the disinfector after treatment. From this building they are passed to the various buildings as directed.

Humorous situations arise from time to time when dealing with the central European. The Medical Superintendent had on one occasion to invoke the aid of the interpreter to prevent the women undressing and going into the shower baths with the men. On another occasion when eight hundred persons were being dealt with the women became terrified in the shower baths and tried to climb over the top of the partitions.

The luggage is transferred from the ship by steel lorries with collapsible trays of suitable dimensions to pass through the disinfectors.

The building is of fireproof construction consisting of concrete foundation walls, concrete columns and floor slabs, the superstructure being faced with red local brick, and lined with terra cotta. The bath unit walls are finished with cement and enameled white, and floors are constructed of concrete and covered with portable wood grids. The waiting and receiving room walls, including administrative offices and boat's crew accommodation are plastered and painted, the floors being hardwood finish. The building is steam heated throughout and lighted by electricity, both of which amenities are generated in the power house with oil burning equipment. The drainage is disposed of by the tidal waters and water supply obtained from the city of St. John.

The accommodation provided includes: (1) Electric lighting plant for Station consisting of a 37½ H.P. oil engine direct connected to 25 K.W. D.C. Generator; (2) heating installation with electrical heating and

Plan of the second floor, showing offices and fan room over the retort chambers.

Heating Detail, Quarantine Station, Partridge Island, St. John, N. B.

compressed air equipment; (3) ventilation system with electric fans; (4) oil fuel storage with pump electrical-ly operated; (5) two disinfecter retorts and cyanid chamber; (6) one auxiliary steam pressure disinfecter cylinder approximately 8 ft. 6 in. in length by 6 ft. in width by 7 ft. 2 in. in height, the chief function of this retort being that of disinfecting the hospital linen; (7) sixteen shower baths with hot and cold water services; (8) receiving rooms with toilets; (9) disrobing rooms; (10) robing rooms; (11) waiting rooms with toilets; (12) administrative offices; (13) accommodation for quarantine boat's crew; (14) stores; (15) engineer's workshop.

Consideration of the fundamental principles of delousing so that the best results should be obtained were given to the disinfecter retorts.

Inasmuch as typhus fever is not transmitted by the bite of the louse, but by a virus which is contained in the excreta of the louse, it is obvious that a method which destroys only the lice and eggs without causing the destruction of the virus in the excreta is not sufficient. Therefore, delousing must be reviewed from the standpoint as that of a process which destroys lice and their eggs and the

virus concerned in the transmission of disease.

Various methods have been employed for delousing such as hydrocyanic acid gas, chloropicrin, and various insecticides, and heat appliances. But since these insecticides are not bactericidal, they must be employed conjointly, or in part, with heat and steam. The disinfectors built at this station are specially designed to take care of such conditions and, therefore, the construction is worthy of notice especially so as they do not operate under pressure.

The construction of the general framework is of wood with the inside entirely covered with mono-metal, the joints being rendered air and fume tight. The doors are of special construction, thrice checked and fume tight.

The heating system consists of 1½ inch pipe coils placed in channels in the floors with steam jets located in such a position as to render efficiently the humidity required for disinfecting purposes, the working temperature being calculated as that of 180 degrees F.

The ventilating system consists of two centrifugal fans, one on each retort, each having a capacity of 1,500 cubic feet of air per minute against

4 inch static pressure and connected to a 2 H.P. motor.

The air ducts are of No. 26 gauge galvanized iron and connected to the chimney stack which rises to a height clear of all buildings.

The cyanid chamber located between the retorts is designed to permit the officer in attendance to operate outside the chamber.

The charge calculated is 3 ounces cyanid per one hundred cubic feet.

When the charge is ready, the fans over the retorts are adjusted for suction and agitation and after the clothing and baggage have been treated the fans are reversed in motion and used for extracting the fumes which in turn are carried away through the main chimney stack.

Such installations as these clearly demonstrate not only the outstanding progress in medical science, but also an earnest desire of the Canadian Government as evidenced by the efforts of Dr. J. D. Pagé, chief of the Division of Quarantine, Immigration (Medical) and Sick Mariners' Service, Federal Department of Health, Canada, to protect the inhabitants of her Dominion from disease, thereby laying a sure foundation for a vigorous and healthy nation.

## The Testing of Cattle for Tuberculosis

That testing cattle for tuberculosis and the cleaning up of infected herds are having a permanent effect in reducing the extent of the disease is shown conclusively by figures recently collected by the United States Department of Agriculture.

The inspectors were asked to supply statistics on the results of three or more tests on badly diseased herds, those that had not less than 10 per cent of reactors on the first test. The first test on more than 58,000 cattle in these bad herds showed that 26 per cent had tuberculosis. Another test six months later on the same herds, from which the reactors had been removed, showed only 6.9 per cent of the disease. By another six months the percentage had gone down to 2.8.

The reports from which these figures were taken show that under normal conditions herds badly diseased may be established as relatively free in a short time. They also show that eradication work can be carried on without destroying the cattle industry. Erratic results were obtained on a few of the 1,882 herds tested, the list of this class containing fewer than 100.

# Public Health Problems in Palestine

## Present Conditions in a Backward Country And the Means Available for Correction

By I. J. KLIGLER, CHIEF BACTERIOLOGIST AND SANITARIAN, AMERICAN ZIONIST MEDICAL UNIT, PALESTINE

FROM the standpoint of public health, Palestine is still at the threshold of its development. Long neglected by an indifferent government and a backward uncultivated people it stands today where most modern states stood fifty years ago. The early phases of sanitation such as public water supply and sewage disposal, which are at present only as unpleasant memories in the greater part of the United States, have hardly been attacked here. But these problems, common to a greater or less degree to all civilized countries, are hardly as serious as those more peculiar to the country and due to various local factors. Conjunctivitis and malaria are responsible for a far greater morbidity than is impure water or contaminated food. It should be added that here as elsewhere the war has left its traces behind it; it has nullified small beginnings toward sanitary improvement and introduced new diseases, such as bilharzia, which were nonexistent before the war.

Sanitation, urban or rural, is still where it was in the United States more than a generation ago. Not a single one of even the larger cities has a sewage system. In Jerusalem

part of the old city is provided with an old sewage system which carries the sewage to the valley of Kidron outside the city wall where it fertilizes abundant vegetable gardens. A small section of the new city outside the walls has also been provided by the Zionist Organization with a modern sewer and disposal plant. But in the greater part of the new city, as well as in the other cities of Palestine, the Arab toilet and cess pit or the old cess pit with a modern flush seat still holds its own. It is a common and not a very pleasant sight to see two natives pumping the contents of the cess pit into a cart or carrying the contents in Standard Oil tins from the pit to the cart. The sewage is then carted away splashing over the streets, leaving a trail and a stench behind it.

### Public Water Supply Rare

Public water supply is also a rare thing. In Jerusalem part of the water is now being supplied by the city, but the watershed is continually exposed to pollution and chlorination is the only safeguard used. Last June Jerusalem was visited for the first time in recent history by a typhoid epidemic that had all the earmarks

of being water-borne. In Safed also there is a beginning of a city supply, but usually the cities still depend for their water on individual wells and rain water cisterns. This system has at least one advantage in a country of low sanitary status, namely, that extensive water-borne epidemics are practically unknown.

Food control is practically nonexistent, and would be extremely difficult to carry out. Milk is still supplied by individual dealers. The cowsheds and dairies are filthy and teeming with flies. The Arab still brings his goat herd to the front door and draws the milk into the customer's utensils, often wetting his fingers with sputum to get a better grip on the teats. But this primitive procedure is indeed just as much a safeguard against extensive milk-borne epidemics as is the individual water cistern against water-borne infections. The meat shops and food markets are wide open and exposed to countless flies that make regular excursions from the public or private latrines near by.

Prevention of infant mortality, prenatal care, control of midwives, that whole phase of modern preventive medicine called by Winslow "Control of Community Infections," as well as that relating to personal hygiene are still untouched.

If conditions in the cities are pre-sanitary those of the urban districts are medieval. The natives are extremely ignorant and superstitious and still live in the same crowded villages in which dwelt their ancestors a thousand or more years ago. The houses are low roofed, poorly ventilated, mud or stone hovels, built partly underground and shared alike by man and beast. In the same dark and dirty room are crowded the family, the goats, and the donkey. The village streets are narrow, crooked, and dirty. There are no toilets; the back of the house or the open field serves the purpose well enough. Flies plague one incessantly and many a child's face is literally black with them.

Living in a land where water is scarce, the native has learned to treasure his water. It seems, in fact

Pumping the sewage from a hospital cess pit to the tank in which it is carted away.

that the villages where possible were built near a spring. Elaborate structures were built to protect this spring. But the water is usually exposed to pollution and near the spring there is always a birka or pool which catches the overflow and serves as an admirable breeding place for mosquitoes.

The Jewish settlements are built on a much more modern plan than those of the Arabs, but the sanitary conditions in most of them are bad. Few of them have toilets; few of them appreciate the need of manure protection; all of them are plagued by flies. The water supply as a rule is fairly good.

An interesting sanitary problem has arisen recently from immigration. Many of the Jewish immigrants who have come into Palestine during the last year have found employment in road building for civil or military purposes. These workmen live in groups of 50 to 250 in camps, scattered all over the country. There is therefore, in addition to the urban and rural problems that of camp sanitation as well.

For a semi-tropical country of low sanitary status the number of important diseases is relatively small. The climate of Palestine is a healthy one and in many respects beneficial. Tuberculosis does not take the toll that it does in the United States or Europe. In fact phthisis is not apparently as common as are other forms of tuberculosis. Scarlet fever and diphtheria are quite uncommon. Hook worm does not exist and only one or two small foci of bilharzia, undoubtedly introduced by the Egyptian Labor Corps, have recently been found. Until this year enteric infections were also uncommon and very mild in character. Venereal diseases are rare among the Jews, but are apparently common among the Arabs. Recently an Arabic village a few miles from Jerusalem was found to be completely infected with syphilis.

The few serious diseases which prevail here are due largely to human carelessness and gross ignorance. The two most important diseases are malaria and conjunctivitis. In addition there are the minor worm infections, dysentery and papataci fever in summer and pneumonia in winter. There are always a few sporadic cases of meningococcal meningitis, typhus and relapsing fever, but since the end of the war they have not appeared in epidemic form.

Malaria is the most serious disease in Palestine. Its prevalence varies

each year according to the precipitation and temperature, but it always occupies first rank in the morbidity records of the dry season. Reliable morbidity statistics do not exist as yet, but some idea of the importance of this infection may be obtained from examinations made among immigrant groups last winter at the beginning of the rain season. Of 170 immigrants who had been in the country six months or less 71 or 42 per cent had already had one or more attacks of malaria; of 68 who had been here six months to one year, 44 or 65 per cent were infected, and of a group of 48 who had been here more than a year 42 or 87.5 per cent had had malaria. This serious condition is in large part created in the cities by the cisterns which offer a splendid breeding place for the anopheline mosquito. In the rural section it is largely a result of open wells, the primitive methods of irrigation in poorly constructed canals, which allow the flooding of the field, and the overgrown stagnant wadis which offer numerous breeding places for the anopheline mosquitoes.

The conjunctival infections are next in importance. Trachoma is highly prevalent, more so in the rural section and small towns than in larger cities. In ten thousand Jewish school children examined in 1913 the incidence was 31 per cent; in 1920 after treatment it was reduced to 20 per cent. But in the rural section the incidence ranges from 50 to 95 per cent. In Beer-Sheba the incidence among

the school children this year was 95 per cent. In addition to trachoma there recur every summer epidemics of Koch-Weeks, pneumococcal and gonococcal conjunctivitis. Crowding, dirt and flies coupled with ignorance and superstition are responsible for this condition, and only time and untold effort can ameliorate it.

A word must be said about the worm infections for though they are usually considered unimportant they seem here to play a significant role. Directly or indirectly they are responsible for many of the intestinal disturbances which occur here. An idea of the prevalence of worm infections may be obtained from the following laboratory examinations. During the months of January to September inclusive there were examined in the laboratory of the Rothschild Hospital 988 stools for parasites. The stools were mostly from clinic patients. Of these 988 stools 492 contained worms, an incidence of 50 per cent. The most prevalent forms were ascaris lumbricoides and trichocephalus dispar; the tenias were less numerous. It is interesting to note that there was only one case of ankylostomiasis and two cases of strongyloides; trichiniasis is nonexistent. Bilharziasis one of the most prevalent diseases in Egypt, has so far been discovered in only two circumscribed areas, and was no doubt introduced during the war.

To cope with the various problems existing here, there are two central organizations: the Government Health Department and the American

A market scene near the Jaffa Gate, Jerusalem, where food control is practically non-existent.

Zionist Medical Unit. Aside from a few small, poorly endowed private hospitals and some mission hospitals, one finds here none of those welfare organizations so prevalent in the United States which contribute greatly toward the advancement of public health. Consequently, practically the entire medical and sanitary work in the country is carried on by these two organizations. But this is not all; not only do the inhabitants fail to initiate any public health reforms, but very often through ignorance or superstition they frustrate the attempts made by either the Health Department or the A.Z.M.U. to improve health conditions.

The Health Department is centrally organized and is responsible for the health conditions throughout the country. The country is divided into districts and in each district there is a responsible principal medical officer with as many assistant medical officers as the budget allows. The general organization of the Health Department is well conceived. There is a quarantine service, an epidemiological service, a central laboratory, a hospital service and a section of vital statistics. But in its details, it falls short in many respects, largely because of lack of funds and sometimes because of poorly qualified personnel. Greater attention is paid to town sanitation because of greater concentration of population, while but little is done in the rural communities. An attempt is made to control water supplies and plans for sewage disposal exist so far only on paper.

The Health Department has thus far not been able to carry out food and milk control. Infant welfare work is negligible and the infant mortality in Jerusalem is between 150 and 200 per 1,000 births. On the whole though considering the limited funds and the magnitude of the problems confronting it, the health department has done reasonably well.

By a tacit understanding, the Health Department has left to the Unit the work in the Jewish colonies and the Jewish labor camps; the care of the Jewish immigrants and the hygiene of the Jewish Schools. But the most important undertaking of the Unit consists in the establishment of a series of district hospitals in various centers. The Unit maintains a first class hospital and nurses training school in Jerusalem, and hospitals in Jaffa, Tiberias and Safed. There are well equipped laboratories in Jerusalem, Jaffa and Safed which are

An open back privy—an advance over the privyless state characteristic of most of the villages and settlements.

doing the bulk of the work for the country.

Important as is this hospital work the Unit has done real pioneer work here in rural and camp sanitation, in school hygiene, in trachoma control and in infant welfare. As was indicated above, rural sanitation was not only unknown here but was looked upon with suspicion. Today wherever the Unit has been able to work, chlorination of water is accepted as a good thing despite the unpleasant taste, sanitary pits and pail privies are gradually being introduced and reduction of flies of proper disposal of the manure is slowly gaining headway. The colonies are divided into groups, and for each district there is a sanitary inspector who is responsible for the sanitary conditions of the settlements. The sanitary conditions of the camps are controlled in the same way by a resident sanitary inspector, who looks after the water, toilet, kitchen, garbage disposal, fly control, etc. There is a department of school hygiene with visiting physicians and nurses which is modelled on the American system. Trachoma control is being carried on in the city schools and settlements. The Unit is at present the only agency that exercises control over midwives. By paying them small fees for all cases they deliver, the Unit is enabled to insist on high standards. It also furnishes prenatal care to the poor through the clinic or through home visits by physicians.

The malaria problem is so serious

in Palestine that the existing agencies and the measures adopted by them for its control deserve special consideration. Again the only organizations actively engaged in constructive work are the Health Department and the Unit. The work of the health department has been thus far extensive in character and superficial. In the cities, untrained laborers, in the main unreliable, petrolize cisterns and cess pits at intervals. Much good has resulted even from this work and a reduction in the malaria incidence is noticeable. In the rural districts malaria inspectors are sent bi-monthly to distribute free quinine to whosoever will take it. The value of this procedure is minimal. The hopeful thing in the government work is its plan and program. It is preparing surveys for active work when and if the funds will be forthcoming.

The Unit has worked more intensively. It has selected a few special areas where experiments in malaria control by petrolization, eradication of carriers, and quininization have been conducted. The results should serve as a guide for anti-malaria work in Palestine. In addition it has done intensive work in a few of the settlements in Upper and Lower Galilee where by removal of stagnant water, drainage and petrolization, settlements that were considered pest holes of malaria have this year been rendered comparatively malaria free. But as is the case with the government, the real work that the Unit can do exists at present chiefly in

Pollution of a watershed by irrigation channels. The water is deflected from the aqueduct to the irrigation canals by a vertical lock. On opening the lock the water from the channels flows back into the aqueduct.

plan, and its execution will depend on the funds available.

### Summary

Palestine is on the whole a healthy country, and could under normal conditions be kept reasonably free from diseases with comparatively small funds. But owing to the backward status of the people and the deplorably neglected conditions of the country certain serious problems exist which are rendered more serious by the steady inflow of a susceptible alien population. The most serious immediate problems are general sanitation and the control of malaria, trachoma and other eye diseases. To cope with these problems neither of the two agencies alone has sufficient funds to accomplish any substantial improvements. The two organizations working in harmony and supplementing each other could rapidly bring the health conditions in Palestine to the level of that other civilized communities. With large funds, the desired results could be attained more readily, but under the present conditions the hope for rapid improvement lies in harmonious cooperation between the two existing agencies for the best utilization of the limited amount of money at their disposal.

### Sewage Disposal on Farms and Country Estates

If the "back to the farm" movement is to become really popular, farm sanitation and sewage disposal must show an improvement over that noted by the state of Illinois in a recent survey of a southern state

which revealed that of 1,501 farm-houses 62.8 per cent had no privy of any kind. Investigations by experts of the sanitary conditions of farmsteads with regard to soil and water pollution has disclosed almost primitive sanitary arrangements. Since upon the farm which supplies food products and milk to the cities the health of urban communities depend, farm sanitation is imperative.

William Paul Gerhard, C.E., Dr. Eng., of New York City has published a pamphlet on this subject condemning practices often recommended by health bulletins. Among these unfortunate recommendations Dr. Gerhard assails the pit privy which pollutes the soil and frequently the water in farm wells or springs and is therefore a constant menace to health.

There are four approved methods of sanitary sewage disposal which are safe as well as feasible for country installation,—the dry disposal system, the liquefying or biological system, the chemical system, and the water-carriage system. The late Col. George E. Waring, Jr., sanitary engineer was the first champion of the "earth-closet" system fifty years ago. This has been in general use in the country districts of England. It can be attached directly to a dwelling in a service wing which is a great advantage in cold weather. The use of "peat dust" because of its highly absorbing powers rather than earth was recommended in a bulletin issued in 1896 by the United States Department of Agriculture. The vast fields of peat in Canada should make this accessible for use in this country.

With both the earth-closet and the

pail system constant care is necessary. Chemical closets have been manufactured in recent years, some of which can be used indoors. As these are expensive a little more money might well be invested to install a water-flushing system. In a water-carriage system the liquids should not be drained into the usual form of leaching cesspool but should be water tight.

### Rhyming One's Way to Good Health

"Apples are good,  
Apples are sweet  
Apples are good  
For cleaning your teeth."

wrote Grant Waldman, member of the open air class of Public School No. 158, New York City. This and many similar rhymes concerning the nutrition of dates, of brown bread, our well known friend Vitamin, of milk, of fresh air, are in the book "Many Roads to Health" published by the Child Health Organization of America and edited by Mary K. Moriarty. The booklet contains pages from the children's own health books in which each day they wrote jingles and pasted with care advertisements illustrating their thought.

"Health was not taught as a separate subject but wove itself into and around the three R's," states their teacher. In the school it was possible incidentally to get the children interested in the rules of the health game. Just before Man O' War's race with Sir Barton at Windsor, Canada, the children followed the details of his training, learned how he was fed certain foods and was given the proper physical care. When he came out victor in the race, this strengthened the children's belief in the health game.

There were twenty-six underweight children in the class. At the end of the year each made his grade and two had made extra grades. Each child had his own weight chart on which a graph was drawn day by day with his increase in weight. At the end of the term from February to June weight had increased from one pound to twelve and a half pounds, with the average gain falling around five pounds.

By means of the scrapbook lessons in cleanliness in the bed room and the kitchen as well as good personal habits such as bathing, brushing the teeth, and sleeping in fresh air were inculcated. To the children it was a most fascinating game.

# Teaching the Farmer Social Disease Control

By MILLARD KNOWLTON, M.D., C.P.H., REGIONAL CONSULTANT, U. S. PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

THE venereal disease campaign like any other campaign for public action must be carried to the people. In a state where most of the people are farmers this means carrying information to the farmer. It is true that the problem may be difficult of solution, but any program will be incomplete and one-sided if it does not contemplate reaching the farmer as well as the city dweller.

There is no doubt some basis for the argument that venereal diseases are more prevalent in the cities than in the rural sections and for that reason the campaign against them should begin in the cities. It is true that cities, especially cities in which there is lax law enforcement against prostitution, serve as distributing centers for distributing venereal diseases throughout the regions round about. While it is natural and easy to begin an educational campaign in the centers of population where the people are readily reached, it is essential that extension of the campaign to the rural sections be not too long delayed. This is especially important in dealing with the venereal disease problem where personal conduct is such an important factor in prevention. Enlightenment may not save all from venereal disease, but it is especially effective in saving the best, the strongest, the most self-controlled from this catastrophe. In weighing the relative importance of city and country as fields for work it must be remembered that only about half the population of the United States live in cities; the other half live in rural sections and small towns.

Accepting the principle that the campaign must be carried to the country, there are certain general requirements for such a campaign that must be met: (1) Traveling.—In the first place it is apparent that whoever has information for the farmer must go to the farmer with it—that a show to reach the farmer must be a traveling show. (2) Motion pictures.—The most effective means of teaching almost any subject is by motion pictures. For years health instruction of various kinds has been given by this means and it so happens that the very best motion pictures on any health subject deal with the venereal disease problem. Therefore motion pictures may well be used in carrying information to the farmers. (3) Lec-

tures.—No appeal is so strong as the personal appeal. A motion picture used for educational purposes is made doubly effective by a good lecturer. In fact, there is reason to doubt the wisdom of using motion pictures for venereal disease instruction without a lecturer present to lend dignity to the situation and see that the right kind of atmosphere is created for presentation of the picture. (4) Educational literature.—An opportunity will be lost if persons who attend such lectures are not given some pamphlets or literature to carry home and read at their leisure. (5) Adaptation to small cities.—It is essential that the plan adopted be suitable for use in small cities, say cities up to 25,000 or even 50,000 population, as well as for use in rural sections. This is necessary to avoid duplication of the equipment for city work, and in order to permit working by county units—completing one county before going to the next. (6) Low cost.—It is essential, of course, to keep the cost within reach in order to make the plan feasible.

## All Classes Reached

A type of equipment that will meet the foregoing requirements is an auto truck carrying an electric generator and motion picture machine. This kind of truck was tried out in North Carolina in the summer and fall of 1920 with marked success. Between August 9 and the last of November five counties—Cumberland, Harnett, Robeson, Hoke, and Durham—were visited and lectures were given not only in the cities but also in the rural communities at convenient locations for all people to attend. Meetings for women were held in the afternoons and for men at night. A colored lecturer also held meetings for colored women in the afternoon and for colored men at night. Thus by the employment of two lecturers simultaneous meetings for both races could be held. At each meeting a brief lecture was given, motion pictures dealing with the venereal disease problem were shown and explained, questions asked by the audience were answered, and finally circulars and pamphlets giving information concerning venereal diseases were distributed. The pamphlets now being used have been prepared with great care and have been found to accom-

plish their purpose admirably. The use of these agencies by a lecturer who can answer questions and explain obscure points makes the campaign very effective. In the larger towns it was found necessary to stay two or more days in order to afford an opportunity for all to attend the lectures. In the rural communities one day was sufficient. Thus most of the time the show was making one day stands and for this reason it was kept moving rather constantly from one locality to another.

Various kinds of buildings were selected in which to hold the lectures and show the pictures. Sometimes it was a church, sometimes a schoolhouse, sometimes a theatre, and sometimes the pictures were shown out of doors to an audience assembled under the starry sky. In one place a tobacco barn was used for this purpose and the mules in their stalls on either side of the area-way used as an auditorium looked out upon the scene.

The people who attended these shows were of all kinds and from all stations in life. Society women sat beside factory girls and learned things of great interest and vital importance to both. The pictures had a message alike for the silk-gowned woman wearing a Parisian hat and the woman clad in a calico wrapper and sunbonnet who came barefooted to the lonely schoolhouse in the pines and chewed her snuff stick while the pictures were thrown upon the screen.

That great interest was aroused in all communities visited is attested by the large audiences, the frequent expressions of approval, the earnest attention given the speakers, and the eager request for literature to be carried home. Occasionally a man with a mistaken idea that women must be ignorant in order to be innocent would object to his sisters or his wife attending the meetings and learning something of the great venereal disease problem. Such instances were exceptional, however. Usually both men and women gave their most enthusiastic endorsement to the program for disseminating information concerning venereal diseases and the methods of prevention.

All together 319 lectures were given in connection with this field car experiment. While the men attending these lectures outnumbered the women almost two to one, there were still a

good many women present as the total attendance was 53,659, or 31 per cent of the entire population of the counties visited. Since approximately one-half the population were not eligible for admission because of youthful age this means an attendance of more than one-half the adult population, which is considered a remarkable showing indicative of unusual interest.

Numerous incidents during the experiment show individual interest in the matter. For example, at one school a woman stopped the show soon after it began and said that if the rest of the picture were as good as the first, she wanted her two daughters to see it. The result was that the audience waited until she went home and brought her two daughters to see the picture. Another place a man from the audience came to the speaker after the meeting and offered a five dollar bill as a contribution to the cause. The man said; "What I have seen and heard here tonight is worth more than a hundred dollars to me and my family and especially to my two boys. If I had learned this lesson as a young man I would have been a different man and would have a different story to tell about my life. I cannot spare a hundred dollars just now but I do want you to take this five dollar bill as evidence of my appreciation for the information you have given me." Of course, his five dollars could not be accepted but it was suggested that he contribute it toward the maintenance of a free clinic for the treatment of venereal diseases. Another man who attended a lecture wished to present the speaker with a jug of "moonshine." As the speaker happened to be "on the water wagon" this also was declined.

On a typical day with the exhibit in a rural community the lecturer and mechanic start out in the morning with the car and go to a schoolhouse or church some miles away in the pines where the exhibit for that day is to be held. No other building is in sight, but the show has been well advertised in advance, and as the lecture hour approaches people come out of the woods and fill the lonely school or church with an eager audience that is all attention when the lecturer steps to the platform and begins to talk. Some of the people came through woods along paths and roads while others merely came through the woods. The wonder is where they all came from.

When the lecture is over they all

have something to say to the lecturer before departing. Some offer congratulations, some want further information and ask various questions. Some request that the exhibition come again, and many of the men say, "My God, I wish I had known this when I was a boy!" The women thank the lecturer for telling them the story and say, "It is a great work you are doing, even greater than the work done by the minister!"

#### Audience's Reactions

At one place a patriarch of eighty-four years got up and said: "I am glad I saw this picture and heard this talk because I can see now how fortunate I have been in having led a clean life. I hope every young man here tonight will take this lesson to heart. We certainly ought to be thankful to the government for the good it is doing with these pictures. There is only one mistake that the state and government have made. They ought to have begun this work fifty years ago." Another man arose, endorsed all that the patriarch had said and continued, "Like him I have been lucky enough to have been a clean man all my life. I am the father of thirteen children including five sets of twins, and all are healthy and sound. I am not priding myself but all I can say is these pictures prove it pays to lead a clean life. From what I know of conditions among men in this end of the country, I can repeat what the patriarch said that it is a pity the state and the government did not get here with this show fifty years ago."

In one town the interest was so great that arrangements were made for pictures and lectures on Sunday night. The churches were closed in order that the members might attend the lectures and learn the great moral medical lessons conveyed by the pictures. When ministers voluntarily offer to omit a Sunday night service in order that their members may be free to attend another meeting it is evidence that the other meeting is regarded as an important one.

This great interest is due to a number of factors. In the first place people appreciate the vital importance of the venereal disease problem and want to know more about it, especially about methods of prevention. In the next place the campaign was organized on such a basis as to bring the matter forcefully to the attention of the public. In the third place, great care was used in the presentation of the whole matter so that the people

were led to appreciate the sincerity and earnestness of the effort.

In working out the general plan of campaign it was arranged that a skilled publicity man should go ahead of the exhibition, make all arrangements for its showing, advertise its coming through the newspapers and by means of placards and handbills so that everybody would have a chance to know about it and thus prepare the way for a successful showing when the exhibition arrived. The field car itself carried three men, a lecturer for white people, a lecturer for colored people, and a mechanician. These men carried out the programs set up and advertised by the advance agent.

As indicated, the work with the field car was carried on as an experiment to demonstrate the value of such methods in educational health work. The idea of conducting a campaign of this kind originated in North Carolina and for that reason when the National Government and the American Social Hygiene Association became interested in the matter it was determined to experiment first in the state where the idea originated. Thus it happened that the experiment was financed jointly by the United States Public Health Service, the American Social Hygiene Association, the North Carolina State Board of Health, and the local communities where the exhibition was held. The field car was purchased and equipped by the American Social Hygiene Association with funds provided by the American Red Cross.

So successful was this experiment in arousing interest and disseminating information that it was desired to organize such a campaign on a permanent basis. With that end in view, plans were formulated for constructing a field car equipment that would weigh about one-half as much as the one used in the experiment. The weight of equipment is of considerable practical importance for the reason that a heavy car mires down or goes through bridges so frequently on country roads as to impede progress materially and sometimes cause the missing of engagements. A lighter car such as the one planned, that would be much more dependable for this purpose.

would be much more dependable.

Unfortunately the failure of the federal appropriation for allotment to states for venereal disease control work by state health authorities has in recent months so reduced the funds available for this work that the plan had to be abandoned.

## Poughkeepsie Bus Terminal

IN the past shoppers from the rural districts have had little consideration and their inconvenience was scarcely appreciated before the days of the automobile when a large quota of the citizenry "took to the road." Towns on the main thoroughfares often draw more than their share of responsibility for the care of the nomadic tribe that travels in automobiles, but here and there cities and towns have provided camps, resting places, and comfort stations which afford a real respite from the dusty road.

The problem of Poughkeepsie, N. Y., was twofold. It is a favorite stopping place for automobilists, being the largest town and the halfway point between Albany and New York City, and the terminal point of some sixteen or more bus lines to neighboring cities. Traffic conditions at congested points became a civic problem in which the Chamber of Commerce became concerned. The plans by which the difficulties were overcome are told by R. W. Budd in a recent issue of *The American City*.

Many of the large busses which made regular trips daily to various towns within a radius of twenty-five miles received and discharged their passengers on busy street corners or in front of well known stores. This not only blocked the streets, but prevented other automobilists from stopping in front of mercantile establishments where they desired to shop. In addition there was the inconvenience of passengers who were required to wait outside on the streets in all kinds of weather.

Quarters were secured in the heart of the city two doors from Main Street and on the main highway between New York and Albany, where there has been opened a bus terminal and public comfort station. An attendant is in charge of the waiting room to give out information, to receive parcels to be delivered to the bus lines, and to check suit cases and bundles. The comfort station is equipped with lavatories, five-cent pay toilets, mirrors, running water, soap, and towels. A freight platform is provided for larger packages as no parcel larger than a suitcase is allowed in the waiting room.

A large parking lot near by is reserved for the exclusive use of the busses. This lot is fenced, is under proper protection, and all busses are required to park there when not actually receiving or discharging passengers. No bus is allowed to park in front of the waiting room until ten minutes before the scheduled starting time. This convenience was taken advantage of by every bus driver, but in order to eliminate the possibility of returning to the old street-corner parking, an ordinance was passed by the common council restricting the parking of cars. Bus drivers and patrons alike are enthusiastic over the conveniences thus afforded by the Chamber of Commerce.

Another difficulty was covered by providing parking, also for the increasing number of pleasure cars which crowded the thoroughfares and side streets. A lot across the street from the bus terminal was secured

and made ready in cooperation with the Board of Public Works. The Chamber secured an attendant to guard the cars parked there. Cars are checked as they enter, and the owner is given a corresponding identification number. No charge is made for this service, but the attendant is permitted to receive gratuities.

With the provision made for the parking of cars and busses, facilities for the handling of freight and small packages, a waiting room conveniently located, a comfort station modern and well equipped, attendants courteous and always ready to give desired information, Poughkeepsie's welcome leaves a lasting impression that the city's interest in her visitors extends far beyond the matter of dollars and cents. Each visitor as he leaves for his home town has a satisfied feeling that in turn redounds to the benefit of the city in its industrial, mercantile, and financial growth. Its health aspect is one of great importance.

The government has introduced a bill for the prevention of avoidable diseases in Spain. The bill provides for the compulsory notification of communicable diseases; enforcement of preventive measures especially as regards tuberculosis, leprosy, venereal diseases, malaria, and infant mortality; safe water supplies; creation of food and hygiene laboratories; industrial sanitation; school hygiene; and the appointment of sanitary inspectors. The present public health law in Spain goes back to 1855.

The Medical Society of New Jersey will cooperate with the State Department of Labor in arriving at a just rate of compensation for services given to put into effect the amendment to the Workmen's Compensation Act. The new measure provides for medical and surgical service in excess of the former fifty dollar limit and hospital care in excess of the same figure in cases in which application for such service has been made to the Compensation Bureau. To prevent overcharges in medical service, the state medical society will name a physician in each compensation district to pass on the reasonableness of bills in dispute.

Under the auspices of the North Carolina Tuberculosis Association, with the cooperation of the state board of health, an intensive campaign will be conducted for malnourished children in several counties of the state.

With a traveling public approximating two million tourists a year, the Poughkeepsie, N. Y., Chamber of Commerce rose to its responsibilities and provided conveniences which are well appreciated and redound to the benefit of the city.

# Digest of Sanitary and Hygienic Advance

IN the profession of sanitary medicine, one is either, to employ our expressive American *argot*, "a live-one" or a "dead-one." The "dead-one" is content to carry on his job in the same old routine way, to blunder through in the ceaseless combat against disease armed with the archaic, ineffective weapons of other days and to busy his mind with bootless trivialities, without any higher mental flights than are required to read aloud the impassioned titles in the movies. If such an one ever cogitates at all upon his condition, he probably admits to himself that he is standing still. On the contrary, he is slipping down the hill of achievement at an alarming rate, did he but know it, and it is only a question of time until he will hit the bottom with a sickening thud. Then, perhaps, he will regain consciousness only to realize the incurability of his mental ankylosis. To be sure he may attend the meetings of health officers and may receive a certain temporary mental stimulation from contact with his fellows and the half-baked oratory which is an inevitable concomitant of such gatherings, but you can't drill a soldier just a few days a year and keep him up to the standard of a first class fighting man. It takes work, it takes thought, it takes honest study every single day in the year to keep any professional man up to his job.

The "live-one" realizes that the community pays him a salary to think, to plan, to execute health maneuvers, to lead his people out of sanitary darkness into the land of health, longevity, and usefulness. If he does not do these things he is a total loss. Any really good sanitary inspector is perfectly able to carry on routine work; any really good clerk can tabulate data and do paper-work; but it requires a broad background of knowledge, much careful training, and a high-powered mental alertness to be a real health officer. There are a lot of jobs which some health officers are trying to do which could be performed infinitely better by subordinates. The function of the health officer is that of the coordination of all the forces of his department, the integration of the cogs in the health machine. The "live-one" knows that he cannot accomplish this in a big constructive, broad-angle way unless he studies. He knows that unless he keeps the edge of his mind well

whetted on the ideas of other workers, he cannot think creatively, and that he will be unable to meet the demands of a profession which requires up-to-the-minute mental preparedness, a flexible adaptability of meeting conditions which are altering themselves with kaleidoscopic rapidity. Fundamentally, the sanitary profession embraces a wide knowledge, not only of medicine, but of practically every other science as well, and the hygienist who does not keep well abreast of what is going on in his chosen field is soon hopelessly lost. In his studies he must range over a wide area and he must not confine himself to the narrow limits of one single disease-control problem. Diseases are interlocking with each other and with every other thing which concerns human existence and a knowledge of all is necessary to the attacking of one in a really comprehensive way.

There is a wealth of material printed every day on sanitary subjects, a quantity which it is impossible for the busy health practitioner even to skim through. The "live-one" essays as best he can to follow up the literature of his profession, but to do this properly requires a large library of medical publications and much spare time. Then too, there are the difficulties of language, not to speak of the tremendous amount of chaff which must be winnowed to discover a few golden grains of truth. The "Digest of Sanitary and Hygienic Advance" endeavors from month to month to indicate the high lights in our progress and both "live-ones" and "dead-ones" will find in it matter of interest and profit. It is by way of being a prophylactic against "dead-one-ism" and a further stimulant to the worker who is earnestly striving to move forward with the vanguard of sanitary progress.

## Paris Green as a Larvicide

An efficient anopheline larvicide is Paris green in the proportion of 1 per cent mixed with common road dust and thrown by hand over breeding areas, the operator standing to windward and relying upon the breeze to disseminate the mixture. Two teaspoonsful of Paris green mixed with twenty-five ounces of dust will control one thousand square feet of breeding surface at the cost of one cent. The application should be re-

peated at intervals of ten days. The operator should wear gloves. The mixture is harmless to vegetation and does not poison cattle since the arsenic is present as a very dilute surface film and the animal thrusts its nose beneath this film while drinking. Such small quantities of arsenic as may adhere to the nostrils will have no other effect than that of a good tonic.

## Delayed Constitutional Syphilis

Almost all the published collections of congenital syphilis deal with the disease in babies or in children under fifteen years of age. Spackman (*Lancet*, cciii, July 8, 1922) reports the treatment of ten cases of delayed congenital syphilis occurring in males, the youngest of whom was twenty-one years of age, the eldest thirty-one and the average age was twenty-one and nine-tenths years. The author believes that *syphilis hereditaria tarda* is not a rare disease condition and should be diagnosed much more frequently in adult life than it is at present. Aortitis and aneurysms may have a congenital origin and need not necessarily be the result of acquired syphilis, thus again affording an example of the fact that it is the innocent who pay, and that persons who have hitherto been considered perfectly well may suddenly present the symptoms of congenital syphilis when exposed to a great physical and mental stress, such as was so frequent during the Great War. At such times a good many apparently healthy men broke down and showed only too clearly a congenital syphilitic taint. Competent, intensive, thorough treatment is essential to recovery; but, even at best, the treatment of delayed congenital syphilis is apt to be most unsatisfactory and disappointing. Interstitial keratitis, iritis, or choroiditis is often one of the earliest signs and is of great importance in the early diagnosis.

## Community Dental Hygiene

The Health Officer of Cambridge (England), a city of about sixty thousand inhabitants, in his annual report for the year 1921, records the very notable work which he is doing in the solution of the dental problem of his community. A chief dentist, with

one assistant and two dental attendants, cares for the teeth of all school children (of whom there are about 7,800), does the dental work for all expectant and nursing mothers, and makes a quarterly inspection of the teeth of pre-school children. This is a good example of what may be accomplished by intensive public oral hygiene. Although he does not say so, this health officer must have stripped this work down to bare essentials, since the number of persons receiving dental care was so large—a wise and economical proceeding.

### Diagnostic Reaction for Mediterranean Fever

In a note presented to the French Academy of Sciences, Dr. E. Burnet, Sub-Director of the Pasteur Institute of Tunis (*Rev. Tun. des Sc. Med.* February, 1922), proposes an easy procedure in the diagnosis of Mediterranean fever. This consists of an intradermic reaction made with one drop of filtrate of a bouillon culture of the *Micrococcus melitensis*. Until this diagnostic test was brought forward, reliance was placed either on a hemo-culture or the serum reaction, both of which require good laboratory facilities. The intra-dermic reaction has the enormous advantage of being applicable by physicians far remote from laboratories. The positive reaction appears within seven and reaches its full development the following day, persisting for several days.

A BEAUTIFUL CITY WITH DIRTY ALLEYS is like a beautiful woman with unbathed feet.

### Good Health Has a Definite Personal Value

Many a man has failed in business because of some wholly avoidable disease and many another has not been able to advance in life because of the cost of a chronically sick family. The banks frequently will not loan money to a person in poor health. In some sections of the country, a sanitary privy is a pre-requisite to a farm loan. Bad teeth, foul breath, a pimply complexion and a generally subnormal condition have been the undoing of many a salesman. Any health officer who will demonstrate these facts clearly to his clientele will do good since there are a good many people who can be stimulated into health habits if they can

be made to see that it pays. It is not difficult to demonstrate and measure in mathematical terms the direct relation between community health and community wealth. One of the most graphic ways of accomplishing this is to plot the deaths of the community per thousand of population against the bank clearings of the community also per thousand of population, for the same periods of time. It will be found that with a lag on the part of the bank clearings curve, the two curves will be practically parallel.

### The Prevention of Mango Poisoning

*Dermatitis venenata* occurring in persons who have handled or eaten mangoes is a painful and not infrequent affair in the Tropics. Erythema, edema, macules, papules, vesicles, and pustules followed by scaling, pigmentation, and sometimes by actual scar formation, all very similar to the picture of *rhus* poisoning, occur and it has been held that any part of the tree or fruit may produce these results. This is not illogical since the mango belongs to the order *Anacardiaceae* which also includes such irritant plants as the cashew, the pistachio, poison oak, and poison ivy. Simmons and Bolin (*Am. Jour. Trop. Med.* 1, 6, p. 351) include, after a series of excellent studies, that the lesions are not the result of specific protein skin reactions but are produced by non-protein skin irritant, present chiefly in the stem-sap of either ripe or green mangoes. Mangoes may be eaten even by susceptible persons, without the danger of developing dermatitis, if care is taken to avoid contact with the stem sap. The irritant, which is not volatile, may be removed from the skin surface by the early application of ether, followed by 95 per cent alcohol and a phenol lotion to control the itching. Care should be taken not to spread the irritant by the ether or by the use of fatty ointments.

### Occupation and Cardiac Disease

Cardiac workers need not necessarily be limited in their occupation to sedentary pursuits, provided that the type of their occupation is selected and gauged by the condition of the individual's myocardium. Moon (*B.M.J.*, May 20, 1922) is of the opinion that it is important to determine how far a given work suits the

man, i.e., how well he is physically tuned to it, how well he likes it, and the wages therefrom. In deciding the future occupation of the cardiac boy, sedentary work is advisable, since recurrent attacks may occur and boys are apt to overstrain themselves at heavy occupations. Education, training, mental equipment, and temperament are important factors to be considered in making the choice. The important thing is to leave a margin of safety. Mental and emotional stresses are almost as important in the production of cardiac breakdown as physical exertion.

THE HEALTH OFFICER who does not keep his community well vaccinated is like the mariner who navigates without lights.

### Liability of Cholera Vibrio in Sea-water

Various investigators have reported that cholera vibrios survive in sea-water from seven to one hundred and twenty-two days. Flu (*Med. den Burg. Geneesk. Dienst in Ned.-Ind.*, 1921, 3, p. 317) who has studied the question in the Bay and Port of Tandjok-Priok, found that cholera vibrio and typhoid bacilli preserved their vitality uniformly from four to five days. The dangers of bathing or of washing clothing in sea-water contaminated with vessel or shore sewage are, in view of the facts, therefore apparent.

### Yaws in the Philippines

The Commission for the Suppression of Yaws in Parañaque reports its results in 275 carefully studied and treated cases in the *Monthly Bulletin of the Philippine Health Service*, (Vol. II, 2, p. 35 et seq). This well illustrated document shows that 94.5 per cent of the cases were clinically cured, 2.5 per cent were improved and 3 per cent of them were not improved or recurred after treatment. "Out of 258 cases in which the mode of infection was recorded, in 132 the disease was contracted from relatives or playmates. A close personal contact, therefore seems necessary." Many of the cases coming to the clinic were still infected with scabies and not a few of the mothers insisted that the infection started from these lesions. It is therefore not outside the realms of possibility that the *sarcoptes scabiei* may have been the vehicle of transmission.

## The Ideals and Objectives of The Nation's Health

THE two years and more which have passed since THE NATION'S HEALTH established its journalistic service to the field of public health have served only to strengthen the conviction that there is a definite place for a magazine of the type which its founders had in view; and the editorial reorganization announced in the present issue indicates no fundamental change of policy but rather a progressive development along the lines already laid down.

The modern public health campaign is still in the state of flux which characterizes every new movement. The actual application on a large scale of the technic of disease prevention is still only in its beginnings. The financial resources at the disposal of the health executive are likely to be trebled and quadrupled within the next two decades and the machinery for correlating preventive procedures and for controlling the commoner and subtler dangers which threaten the health of the community is being worked out experimentally in various cities from year to year and from month to month. It is of the utmost importance therefore, that news of successful ventures in public health practice should be disseminated as promptly as possible to those who may be interested in imitating them, so that such practice may be developed and standardized as rapidly as possible.

Furthermore, it is clear that the progress which is taking place in the field of public health is tending to produce fundamental changes in the relation between the physician and the community, since the newer lines of health work so often involve the organization of medical services for the early diagnosis and preventive treatment of disease. Even those who are most opposed to what is vaguely termed "social medicine" realize that changes of some sort are imminent, and it is of vital importance to the public, as well as to the physician, that such change be made along lines which will maintain the high intellectual and moral standard and the freedom of initiative which have been the glory of the medical profession, while at the same time recognizing the need for medical organization and the application of medical science to prevention as well as to the amelioration of architecturally completed disease.

The NATION'S HEALTH, in furnishing a forum for the open discussion of the advantages and disadvantages of such practical advances as may be made from time to time, will be bound by no *a priori* theories of policy. It will be guided only by the conviction that machinery for the promotion of health should be very greatly expanded and that the work of the medical profession should, in whatever fashion pleases best, be so correlated with the public health campaign as to become as effective as possible in the prevention and early treatment of disease.

We shall not attempt, on the one hand, to compete with several organs now in the field for the presentation of original research problems in hygiene, either community or industrial; nor on the other hand shall we attempt to appeal to the general lay public. The aim of THE NATION'S HEALTH is to be a magazine of current information in regard to practical progress in the public health field for public health officers, physicians engaged in infant welfare, school hygiene, anti-tuberculosis work or other fields of preventive medicine, public health nurses and social workers, for industrial physicians and industrial nurses, and for institutional authorities and others responsible for the health of groups of individuals. It will hope to supplement the highly specialized appeal of such organs as address themselves specifically to the medical profession or to professional workers in public health, nursing, or allied fields by a comprehensive survey of the whole field of community health promotion, free from the necessary limitations which accompany the advantages inherent in the official representation of an organized professional group.

Through the cooperation of a widely representative group of advisory editors we trust that the

picture of the public health movement to be presented may prove to be a comprehensive one. We can only succeed to the full, however, with a still wider support; and we appeal to every reader of *THE NATION'S HEALTH* to aid us by counsel and criticism in order that we may realize our ideal of playing a real part in furthering during coming years the development of an effective community program for the upbuilding of a physically sound and strong American people.

## Federal Aid for State Public Health Activities

WORK for the promotion of the health of mothers and infants is now going forward in thirty-nine states under the provisions of the Sheppard-Towner Act; and the act has been accepted by three other states.<sup>1</sup> The Legislatures of Louisiana, New York, Massachusetts, and Rhode Island have refused aid under the act, and in Maine the Governor has issued a special proclamation rejecting it. Washington has not yet expressed itself one way or the other.

The opposition to this measure which has developed in certain New England states and in New York is a curious psychological phenomenon. The principle of Federal aid to local activities has been an accepted one ever since agricultural experiment stations all over the country were started in 1887. No possible surrender of state authority can be involved since the only limitation on the use of the funds lies in the provision that the plans for spending the money must be approved by the Federal Board of Maternity and Infancy and if there were any chance of unreasonable dictation (which there is not) the state could of course withdraw at any time from its cooperation. That the objectives in view are sound and that there is money available for their pursuit is indicated by the fact that Maine, Massachusetts, and New York, while refusing the Federal money offered to them have made special appropriation to carry on for themselves the special work contemplated under the Sheppard-Towner Act, thus recognizing its essential wisdom.

There seems indeed to be little intelligent basis left for opposition to the Sheppard-Towner Act or for any resentment against Federal initiative of the sort which it represents. After all, the government at Washington is not an alien tyranny but as much a part of our own political life as the government of our states and cities. To the public health worker the type of Federal leadership exemplified in this bill is full of promise. The

system of national grants for cooperative local health activities is basic in the magnificent system of Great Britain. Under the Chamberlain-Kahn Act the same procedure was used for the upbuilding of venereal disease clinics in a way which constituted one of the most notable public health achievements ever accomplished in this country; and the Sheppard-Towner Act is likely to yield results of even greater magnitude not only in the states which have accepted it but also in those which while rejecting Federal aid have been forced by the act into making their own appropriations for carrying out its purposes.

## Personality in Public Health Publicity

A KITCHEN table will fly if given adequate and suitable motive power. Any fool with sufficient bicepital development can sail a kitchen table a short distance through the air but it will hit the ground with a crash that probably will demolish utterly that humble piece of household furniture. It takes imagination, brains and application to rig a machine which will lift a kitchen table from the floor and make it fly safely to a given destination.

Similarly, public health will fly if given adequate and proper publicity but it requires imagination to present it to the public in palatable form, brains to know what are the important things to stress in the propaganda, and an intense application to maintain the flow of necessary and valuable matter. The old days of public health exhortation are passed and the modern health propagandist has learned to bait his hook in such a way as to secure the greatest number of "nibbles" and "bites." The campaign of education by publicity has now reached a highly technical stage.

Any fool can brazenly crowd his public health ideas into the public prints for a while, and if he keeps at it with sufficient news-sense, it is surprising how long he can keep handing out spectacular tosh. As a rule, such a one is not seeking public health publicity but is engaged in personal propaganda, and sooner or later he tries it once too often, only to have the propaganda which was to have served as stilts to lift him artificially above the herd, transmute itself into a boomerang to injure him who hurled it.

There are certain symptoms upon which an almost infallible diagnosis may be made between public health propaganda and personal propaganda. Good health propaganda is largely impersonal so far as the author is concerned. It tells the facts in a convincing way, in simple language which even a child may understand, and with the

<sup>1</sup>Thirty-one states by provisional gubernatorial acceptance; 11 by legislative action.

punch of the story in the first seven lines. It takes a single idea and it hammers, hammers, hammers on it until it drives it deep into the public mind and clinches it there ineradicably. Sometimes with humor, sometimes with bald, rude strokes, sometimes by gentle insinuation, it strives to sink home a lesson in personal or community hygiene but always the big idea is the health salvation of the public.

On the other hand, when a news story begins, "Health Commissioner Jones said today that ingrowing toenail constitutes a serious health menace," or "That ingrowing toenail is a health hazard to future generations," was the keynote of the address of Smith Brown Jones, M.D., Health Commissioner of Squedunk today, or "Care for the feet if you care for the future" was the slogan presented by Health Commissioner S. Brown Jones to the Interurban Shoe Manufacturers Association today, it is highly evident that Jones is getting in a few good licks for Jones primarily, and for the public incidentally.

In all fairness though, it should be interpolated, that there are some personalities which in themselves are news and a health worker should not be classified as an autogenous advertiser merely because his name adorns the public prints at frequent intervals. Some people are always a good story. Their simplest act contains that intangible dramatic, histrionic, arresting quality which always excites interest. Theirs is the privacy of a bird in a cage, and if one of these unfortunates remarks that "it's the humidity we feel rather than the heat" or happens to shoot a birdie on number four, it becomes copy at once for the news-grubber. This type of man is often far more entitled to our sympathy than our censure and he is frequently a great asset in a health publicity campaign since he can always attract immediate attention through the press, but for that other for whom he is so often taken, that brazen, climber-sanitarian, that indefatigable limelighter, crowding out the baseball news with his blatancies and assaulting our intelligence with half-baked truisms and purloined truths, there is no inferno too deep.

There is an opposite type, quite as filled with conceit and infinitely less valuable to the health education of the public than either of the types described above. It is the self-contained, repressive prig, masking his overweening self-esteem with hypocritical modesty, the man who doesn't believe in health advertising, or in the use of the simple vocabulary of the flivver-driver, who considers it *infra dig.* to approach the public through the avenues of the press, who has nothing but a sneer for the worker who is seeking to make

health an humble household word. Such a man is a brake on the wheel of progress.

As a matter of fact, a combination of these three types is about the ideal. The personal publicist, the arresting personality, and the conservative type which never holds its cards save at the vest, these balance and counterbalance one another, checking the on-rushing ego of the one, tempering the picturesqueness of the other, and stimulating the inhibitionist to the promulgation of the doctrine of clean, safe, healthy living.

### Autogenous Smoke Consumption

THE greatest of all human problems is the handling and treatment of the human sick, greatest because it is so human, and unless it is approached with a deep appreciation of the human factors involved, its solution is difficult if not well-nigh impossible. The French, with an apt facility for coining adroit phrases, speak of "putting one's self in the other fellow's skin." This means more than getting the viewpoint of another, more than seeing eye-to-eye with him, more than making your mind walk hand-in-hand with his. It means the attuning of yourself so completely with your fellow men that you will know the things which will harm him, the things which will grate upon him, and the things which will anger him. It means a knowledge of his weakness and his strength without unkind analysis, an understanding of his mental processes and reactions. From this flows the corollary of doing nothing which will harm him, grate upon him or anger him. It is a quality all too rare in those who come into contact with the sick. Its possessors are the successful physicians, hospital administrators and nurses, while those who have it not are the misfits of the profession.

How easy it is to lose sight of the fact that the great bulk of the hurts which we inflict upon others and which others inflict upon us are not intentional or preconceived, but rather are they the result of carelessness—the quality of caring less for our fellow than we should. It is a very easy matter to wound a sick person with an idle phrase or perhaps even to turn the tenure of his life with an idle jest. To the nurse or doctor, "putting yourself in the other fellow's skin" means, so far as the patient is concerned, the minding of one's own business strictly to the exclusion of gossip, the guarding of speech and comport with careful consideration for his feelings and reactions, the regarding of his weaknesses with the kindly eye of charity, and the living and working with the sick in harmony.

Closely akin to this is the ability to consume your own smoke. This partakes of the quality of equanimity. It is the characteristic of taking the buffetings of life without whining or self-pity. It is the sign of adult development and the doctor or nurse who lacks it would do well to learn autogenous smoke consumption instead of belching it forth in black and noxious clouds, remembering that there is just as much smoke to be purified in the sweet moment of success as in the bitter hour of defeat and that the smoke of victory is even more offensive than that of failure. Furthermore, students of thermo-dynamics have long ago learned that the black clouds of smoke indicate a frightful waste of energy and sanitarians know the disastrous effects supervening upon continuous exposure to smoke, which in addition to being an extravagance and a health menace, is an infernal nuisance. People may, to a certain extent, be measured by this yardstick. Some run along so smoothly, without friction or a hot bearing, and with so little evidence of any combustive process that they may be classed as thoroughly efficient machines. This is the ideal attitude of those who treat or nurse the sick. Others creak with every added load, no matter how small, and fill their entire environment with the vaporings of their half-stoked fires. Their place is far from the bed of pain, distantly remote from the places sought by the sick seeking relief from physical and mental distress.

### The Journal of Personnel Research

THE first issue of *The Journal of Personnel Research*—which made its appearance in May promises well for the future of the Personnel Research Federation, whose official organ it is, and for its value as a tool in the hands of editors, administrators, and students everywhere who need to work with and understand human beings. Reasons both scientific and practical for personnel research are presented as the leading article by James R. Angell, president of Yale University, and Alfred R. Flinn, secretary of the Engineering Foundation and of the Personnel Research Federation, gives a brief history of the development of the Federation, of the several agencies united in the project, and of the different lines of work at present under way, while the basic principles of vocational guidance are treated by C. S. Yoakum, Carnegie Institute of Technology. To quote Yoakum, "the problems of personnel are dependent for their solution upon many investigators working in many communities. These solutions will be expedited if the investi-

gators are in communication, and if their work is coordinated."

The Foundation is designed to bring about such coordination. Interest in the subject of personnel will be quickened, science will be substituted for ignorance, and intelligent choice for haphazard selection when the results of personnel research are properly interpreted and generally applied. We approve the enterprise and commend the journal.

### Laveran, 1845-1922

METHODICAL, indefatigable industry, stimulated by a Gallic imagination and a high moral courage tempered by a scrupulous, scientific honesty was the outstanding feature of the character of Laveran whose life of wonderful accomplishment has only recently drawn to a close. He gave to the world the mastery of the disease which caused the decadence and fall of Greece and Rome and opened the most insalubrious regions of the world to the enterprise of man. As a result of his labors the Panama Canal became an actuality and great fertile but uninhabited areas in many parts of the world which lay waste by reason of an eon-old endemic, were opened to colonization and transformed into healthful and productive gardens. His discovery of the causal agent of malaria blazed the trail to the rational prophylaxis and eradication of the disease thus constituting a basic addition to the sum of human knowledge and another safeguard to human existence.

Science has lost one of its most illustrious servants and France one of the most brilliant names which ever illuminated the already dazzling page of that nation's scientific achievements. That simple, modest son of an Army Medical Inspector, alumnus of the School of Strassburg, teacher and director at Val-de-Grace, army medical officer, worker at the Pasteur Institute, labored in the cause of humanity to the end of his seventy-seven years and, weighted with every honor which science and a grateful world could bestow upon him, passed into the company of the medical immortals, leaving behind him a world which was safer and healthier than he found it, a name which will never be forgotten, and an example for all who would serve their fellowmen.

From the beginning of his medical life, Laveran set for himself the invariable rules of punctual, methodical work each day, scrupulous care in the fulfilling of his scientific and moral duties, tenacity in research and exactness in observation, and an invariable probity in the expression of that which he had seen and proven. In 1875 he

published a treatise on "The Diseases and Epidemics of Armies," growing out of his lectures at Val-de-Grace, and on November 23, 1880 presented to the Academy of Medicine his first note "Upon a New Parasite Found in the Blood of Many Patients Attacked by Palustral Fever." This note and those following it, addressed to the same body, and to the Academy of Sciences, passed almost unnoticed in France at the time but today they are considered historical events of the first order.

Pasteur was revolutionizing medical doctrines. The causation of disease by the multiplication of a living virus in the living body had captured the imagination of the scientific world. Microbes, bacilli, bacteria, micrococci were being everywhere sought and the Italian physicians, following the methods of Pasteur were describing a bacterial cause of malaria. Laveran, after an excellent training in microscopy, had just been sent from Val-de-Grace to Algeria where malaria was the dominant endemic. The melanemia of the patient was then the enigmatic signature of paludism and Laveran attacked the problem with the idea of discovering how this pigment was formed. In the course of his daily examinations he observed near the melaniferous leucocytes, spherical, hyaline, corpuscles, non-nucleated and pigmented and in very characteristic crescents. "I had seen these things in my examinations," said he, "and I hesitated to believe that these elements were parasites. However, on November 6, 1880, in examining the spherical, pigmented bodies, I observed from the borders of many of them mobile filaments or flagellae having extremely active and varied movements, thus leaving no doubt as to the animal nature of these elements."

This conviction grows from day to day as he notes the constant presence of these same elements in the blood of patients suffering from malaria. He collects his data; he describes and draws the organism with his customary sincerity; he announces without hesitation its specificity, an act requiring a splendid audacity and self confidence thus to announce the discovery of the first example of a sporozoon pathogenic for man, a new and unclassified organism. Naturally the idea was received with scepticism and incredulity. Laveran with perserverance and unshakable faith accumulated further facts and confirmatory data from many parts of the world and on December 30, 1889, the Academy of Science voted him the Breant prize.

After the discovery of the hematazoon of malaria, Laveran sought to ascertain its residence outside the body of the sick, its manner of leav-

ing its habitat to infect the well, the agency by which malaria is spread, and in 1884, reasoning from the discovery of Sir Patrick Manson that mosquitoes spread filariasis, he suggested the existence of an intermediate host in malaria. Followed the work of Ronald Ross, of Bignami and Bastianelli, of Grassi, of Manson and Ross and of many others, and the prophylaxis and eradication of malaria was placed upon a scientific basis and became wholly realizable.

Laveran was elected to the Academy of Medicine in 1893, to the Academy of Sciences in 1901, and in 1907 received the Nobel prize. From 1896 to the day of his death he worked at the Pasteur Institute on the pathogenic protozoa of man and animals and in 1912 published his very valuable work on the subject. The War found him too old for service with the colors but he continued without intermission his labors in the almost deserted laboratories and in 1917 published his splendid book on Leishmaniasis. He founded the Society of Tropical Pathology and presided over its destinies for twelve years and at the time of the centenary of the Academy of Medicine he was its President. Retiring in 1921, he continued nevertheless to follow and direct his research laboratory at the Institute and death alone was able to impose upon this indefatigable worker a definite rest.

### Mr. Lapp Retires as Managing Editor

THE October issue of THE NATION'S HEALTH marks the retirement of John A. Lapp as managing editor. While this of necessity implies a diminution of direct activity and a relinquishment of immediate responsibility, we are glad to say that the presence of Mr. Lapp in an advisory capacity on the editorial staff of Dr. Winslow, assures for our readers the same security in matters of medical legislation and jurisprudence, and the same authoritative sources of social survey that have given character and balance to his editorial work in the past. To the soundness of his judgment and the clarity of his vision much of our prestige is due, and it is a matter of much satisfaction that freeing him for wider activities does not divorce him from the future of the enterprise he has so ably directed in the past. The present change is the culmination of his well laid plans and it is expected that the reorganization now in effect in the editorial board of THE NATION'S HEALTH will give greater force and better unity to the presentation of public health materials, and provides an unusually able advisory board for comprehensive survey of related social and scientific fields.

## The Hazards of Carbon Monoxid Poisoning\*

Preliminary Sanitary Studies Are  
Best Basis for Safety Engineering

BY YANDELL HENDERSON, PH.D., PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY, NEW HAVEN, CONN.

WITH every advance in industry and the arts there is liable to be associated some new physiological strain or health hazard. This has been true of machinery, of the chemical industries, of electricity, of illuminating gas, and it is now proving true of man's latest and most widely used utility, the automobile. The risks involved with the automobile are, however, almost universal. The loss of life in accidents, as reported in the daily papers, is so common that it is receiving serious attention, although effective measures of amelioration have not as yet been adopted, as every one knows.

It is not very generally realized that the exhaust gas from automobiles constitutes scarcely a less serious hazard. Fortunately, however, engineers are beginning to recognize that the sanitary side of large public undertakings and even of some private developments deserves study, and the public is learning to expect this protection. Accordingly, when plans were made for the construction of the first long vehicular tunnel in this country these plans included extensive investigations of the basic facts necessary to the ventilation of such a tunnel, so as to render the air not only safe but practically innocuous to its passengers. This is of special importance, as such tunnels will probably, to a considerable extent, replace

bridges in the future, both because of their cheaper construction and because they do not obstruct the waterways.

The commissions of the states of New York and New Jersey charged with the construction of the vehicular tunnel, or rather tunnels, under the Hudson river at New York arranged with the United States Bureau of Mines to undertake these basic investigations. The work was divided into several special problems, of which we need here consider only two, namely: (1) The amount and chemical composition of the exhaust gas produced by various cars under various conditions of speed, load and temperature, and (2) the physiological effects of the substances in exhaust gas and their allowable amounts not involving appreciable ill effects when such gases are breathed.

### Sacrifice to Secure Speed

The first of these problems was placed in the charge of Mr. A. C. Fieldner at the Bureau of Mines Experiment Station in Pittsburgh. An extensive investigation carried out by him and his collaborators has shown that to a large extent the deleterious character of the exhaust gas of automobiles arises from the tendency of drivers to adjust carbureters so as to afford a maximum of power rather than to utilize fuel with the maximum efficiency. The gasoline mixtures used are generally much richer than would be best, both from an engineering and

sanitary standpoint. More easily adjustable carbureters and greater use of the adjustments so as to attain the required speed and power with a minimum of fuel would not only result in reducing the waste of gasoline but in an exhaust gas distinctly less injurious to health. These investigations show that approximately one-third of the fuel value of gasoline is wasted and that the carbon monoxid, the particular toxic constituent of exhaust gas, averages about 7 per cent.

As regards the total quantity of exhaust gas produced, it is sufficient to say that most passenger cars, with the usual carbureter adjustment, produce from 1 to 2 cubic feet of carbon monoxid per minute. This, in my opinion, could be and should be greatly reduced. Indeed, if the air in crowded city streets is not to become even worse vitiated than at present, passenger cars and trucks must be so constructed that their drivers will themselves feel the need and advantage of varying carbureter adjustment in traffic and on hills almost as freely as a driver now moves the throttle.

The second problem above mentioned, the strictly sanitary problem, which was assigned to me for investigation was worked out with the collaboration of Dr. H. W. Haggard and Dr. A. L. Prince in my laboratory in Yale University. Our investigations have completely confirmed the conception of Haldane, the great English investigator, who has done so much to

\*Read before the eleventh annual meeting of the National Safety Council, Detroit, Mich., August 31, 1922.

decrease injuries and fatalities among coal miners, that carbon monoxid does not form a permanent compound with the red coloring matter, or hemoglobin, of the blood, but competes with oxygen. The affinity of carbon monoxid for hemoglobin is about three hundred times as great as that of oxygen and it is capable, therefore, of rapidly displacing oxygen from the blood and causing asphyxiation and finally death. But by a reversal of the competition, carbon monoxid can be again displaced by oxygen when a person who has absorbed a certain amount of gas breathes pure air or air enriched with oxygen. Our investigations also show that carbon monoxid has no other toxic characteristics except its combination with hemoglobin and exclusion of oxygen; it has no direct effect upon nerve cells. All of the nerve degenerations induced by carbon monoxid are due to asphyxia. Dr. Haggard has indeed even succeeded in growing pieces of chick brain (taken directly out of an egg and suspended in a little chicken plasma) in considerable amounts of carbon monoxid. Animals such as flies and other insects which have no red matter in their blood are entirely immune to carbon monoxid.

Our investigations show further that when gasoline distilled from petroleum is used, practically the only toxic constituent in the exhaust gas is carbon monoxid. When, however, benzol and probably other related substances are present, as in some of the automobile fuels now sold, the amount of these substances escaping in the exhaust gas adds decidedly to its toxicity.

Our investigations were carried out at first on ourselves and the other members of the investigating staff in an air tight room lined with sheet iron. The data so obtained were later confirmed by large-scale experiments in which a dozen or twenty people at a time sat or moved about in a garage building in which a Ford car was installed. A drop of blood was drawn from a finger and analyzed for carbon monoxid, the pulse was counted, the volume of respiration measured and the effect of exercise, after running up and down four flights of stairs, was noted. A test for steadiness was also used, for in carbon monoxid poisoning the victim is quite often unaware that anything is wrong until his legs give way and he falls, unable to rise again.

The best of all indications proved, however, to be the headache induced by carbon monoxid. This is a characteristic oxygen deficiency phenome-

non, observed at great altitudes, on mountains, or after high airplane ascents. It is induced in nearly all persons by certain degrees of saturation with carbon monoxid, although there are some individual differences in the exact point at which it appears. It is usually of the throbbing frontal type, more rarely occipital. It easily passes into nausea, vomiting, and prostration and is accentuated by exertion. Men in this condition lose judgment and self-control, they may become hysterical or even violent; often they behave as if under alcoholic intoxication. The time at my disposal today forbids a detailed description of theory or experiments, but data were obtained sufficient to allow the scientific law controlling the absorption of carbon monoxid from the air in the lungs to be formulated, so that we now know precisely the conditions involving slight and great danger and also the conditions which are safe and practically harmless.

#### Rules Derived for Use

From this law the following rule was derived for practical use: When the time is expressed in hours and the concentration in parts per 10,000 there will be no appreciable physiological effect when the product of the time is multiplied by the concentration equals 3; when the product of time by concentration equals 6 there will be in some persons slight effects; when it equals 9 there will be in nearly every one a distinct effect; when it equals 15 the condition is dangerous. A concentration of carbon monoxid not exceeding 4 parts in 10,000 (that is four cubic feet of carbon monoxid in 10,000 cubic feet of air) is therefore recommended as a practical standard for vehicular tunnels. This involves an enormous ventilation and force to maintain it, but is said by engineers to be entirely feasible.

It is quite certain that this standard is very often exceeded in garages and automobile repair shops where, unless there are special provisions for ventilation, high concentrations of exhaust gas are common. Severe headaches are extremely frequent among mechanics and others who work around automobiles, so much so that repeated partial asphyxia today is a distinct health hazard in this field.

Our observations indicate also the character of the hazard in the small private garage. During the winter months, in the northern states, fatal asphyxiations in such private garages are unfortunately quite common. The owner starts his car before opening the doors, in order to get the engine

warm. If the garage is 10x10x20 feet, giving a capacity of 2,000 cubic feet, and the car produces one cubic foot of carbon monoxid per minute it requires only one minute for the concentration which we have recommended for the tunnel to be reached and in five minutes the atmosphere contains 20 parts of carbon monoxid in 10,000 of air—an amount sufficient to induce asphyxiation. Of course, if the car continues to run the concentration mounts steadily toward a rapidly fatal amount.

In addition to our experiments on men, which could not, of course, be pushed beyond the point of severe headache, we performed an extensive series of experiments on animals which we carried to the point of extreme or even fatal asphyxiation. These experiments were performed with pure carbon monoxid, with exhaust gas from automobiles, and with illuminating gas. They show that while carbon monoxid is practically the sole toxic constituent in exhaust gas from pure gasoline, the gasoline now sold in some places mixed with coal distillate containing benzol, produces a much more toxic exhaust gas.

Gasoline vapor itself has been found in our experiments to have qualities somewhat like those of the ethyl ether used in surgical operations. It is an anesthetic, but the initial stage of excitement passes through a very narrow region of full anesthesia into convulsions ended by death. In the toxicity of exhaust gas, unburned gasoline is not an appreciable factor. Workmen are, however, sometimes overcome when they go into a large tank in which gasoline has been stored. Benzol is much more toxic, as Dr. Alice Hamilton has recently pointed out.

Our investigations with illuminating gas have shown that, while the principal toxic constituent is carbon monoxid, about 20 to 25 per cent of the toxicity is due to benzol and related substances. These substances are to a large extent the illuminants which the laws of many states still require to give luminosity to the gas flame, a requirement which the introduction of the mantle burner has made unnecessary. From a health standpoint this requirement is now perhaps even unwise.

These investigations have also led us on to the study of the treatment of carbon monoxid poisoning. Obviously, the first step in any treatment must be the restoration of spontaneous breathing if it has stopped. For this purpose the manual prone-pressure method of artificial respiration is to

be recommended above any apparatus, for it is as effective or even more effective than apparatus and it can be applied instantly, while the bringing and adjustment of apparatus involves delay. A delay of even a couple of minutes after breathing has stopped may sometimes be fatal and a quarter or half an hour always fatal. This delay has probably cost more lives than such apparatus has ever saved and many such lives might be saved if everyone were trained to perform the manual method.

The next step after restoring spontaneous breathing is to accelerate the elimination of carbon monoxid from the blood. For this purpose the inhalation of oxygen has long been recognized as the specific procedure. But the difficulty arises that after a long exposure to an atmosphere containing carbon monoxid, respiration is very much depressed and the inhalation of oxygen has no stimulating effect upon the volume of breathing. It occurred to us to utilize the stimulating action of carbon dioxide, or carbonic acid, the gas used in soda water and other carborated beverages. In a series of experiments on dogs we found that in animals which were brought almost to the point of death and then allowed to recover spontaneously in air the period of elimination of carbon monoxid from the blood required several hours. When the subjects were made to inhale oxygen the rate of elimination was at first not very much more rapid, the reason being that the oxygen was inadequately inhaled. When, however, a small amount of carbon dioxide was added to the oxygen a very active breathing was induced, by which the lungs were so effectively ventilated and the oxygen was given so free an opportunity to act upon the blood that after a period of a quarter to half an hour nearly all of the carbon monoxid had been eliminated from the blood.

Recently the American Gas Association, representing the illuminating gas interests of the country, requested Dr. C. K. Drinker of the Harvard Medical School to organize a commission for investigation of the subject of resuscitation from illuminating gas poisoning. Dr. Drinker invited my associate, Dr. H. W. Haggard, and myself to serve on this commission and the American Gas Association has generously supplied the funds needed for a thorough investigation of the efficacy of the above mentioned treatment. The Consolidated Gas Company of New York City gave us invaluable assistance by placing at our service its emergency auto trucks and their crews. Health Commissioner Cope-

land and the hospital authorities of New York City gave us their cordial support and cooperation. We were thus able to apply the method to a sufficient number of cases of illuminating gas poisoning to show its efficiency.

The results in a majority of cases were even better than our laboratory experiments had been. Asphyxiated patients who were reached within half an hour—and the utmost speed at this time is essential for success—and who were given an inhalation of oxygen containing 5 per cent carbon dioxide were practically freed from all but the merest trace of carbon monoxid in their blood within twenty-five to thirty minutes. Frequently, also, consciousness returned within this time and within a few hours the patient was practically well again. It is also noteworthy that not a single patient thus treated developed pneumonia, which is so common after gassing, nor any of the other distress-

ing sequelae sometimes associated with poisoning by illuminating gas or the exhaust gas of automobiles.

There are thus solid reasons for the expectation that with the general introduction of the oxygen and carbon dioxide inhalation, fatalities from carbon monoxid may be very considerably decreased and its after effects largely eliminated.

## Feeling Tone in Industry

PAIN and fatigue are the physical and psychic conditions we are endeavoring to avoid throughout our lives. The absence of pain must be assured by a sense of physical well being and by safe and sane working conditions before work itself is undertaken, and during the progress of the day's work any undue sense of fatigue on the part of the worker is registered objectively by the decreasing amount of work done, or by its falling off in quality. B. Muscio<sup>1</sup> declares, however, that feelings of fatigue are not reliable criteria of the capacity to work, for increasing and not decreasing amounts of work may be done under conditions of fatigue; conversely, the work may deteriorate both in amount and quality prior to the onset of feelings of fatigue. The feeling of fatigue, therefore, has been abandoned as a possible fatigue test and also is now disregarded in investigations of characteristics of normal working activity.

This is not saying, however, that feelings of fatigue bear no relation to activity or to output. Data were obtained by Muscio from two groups of women: (1) Twenty women medical students in work exclusively mental over a period of five days; and (2) fifteen women typists over a period of three days. The subjects naturally were not trained in self-observation.

<sup>1</sup> *Feeling Tone in Industry*: B. Muscio, *Brit. J. Psychol.*, October, 1921.

In the typists the output curve increased steadily throughout the first part of the morning notwithstanding increasing feelings of fatigue. Otherwise there was a striking similarity in output curve to the curve for feelings of fatigue.

The natural response to feelings of weariness is to slacken effort or to cease work altogether, which leaves the explanation of the output not being in agreement with the fatigue curve to the operation of incentives and warming up (dynamic relation to the will of the worker). Extraneous incentives, however, fail when the work becomes obviously painful. The degree of fatigue before a slackening of work occurs differs in different individuals, and for the same person it differs at different times, but generally it will be related directly to the strength of incentives.

These feelings of fatigue may play a far greater part in normal work than current "fatigue" investigators, engrossed with physiological problems, recognize. Muscio suggests that "feelings" generally, and not merely "feelings of fatigue" should be accorded more notice in connection with various sides of industrial life than they at present receive.

Simmons College announces a two year pre-medical program arranged to meet admission requirements of Class "A" schools.

# New Jersey Industrial Rehabilitation Clinics\*

BY GENERAL LEWIS T. BRYANT, COMMISSIONER OF LABOR OF NEW JERSEY, TRENTON, N. J.

THE subject of "Industrial Clinics." cannot well be covered without a word or two regarding the system under which the Department of Labor of New Jersey is operated. This is especially necessary for the reason that the principal parts of my address will consist of describing several branches of activity, which are so closely related to the one fundamental principle under which we are working; that is, to take the worker as we find him and, first, physically rehabilitate him to the fullest extent possible, equip him with artificial limbs or other appliances, then give him such training as his disability will permit, and then, place him in such a position as will enable him to earn his living—not as a mendicant, but as a self-respecting citizen in competition with his fellows.

New Jersey was one of the original states to pass a Rehabilitation Act. It was drawn so as to give the Commission tremendous latitude in working out its methods. The Commission, having no precedents to follow, approached the subject from the purely educational standpoint. However, the more we went into the subject, the more we became convinced that our job was not merely to rehabilitate the man so that he could go out and earn his living in spite of his handicap, but, by means of an operation, therapeutic measures and esthetic appliances to make the man physically better so that he would be capable of filling the position that he had previously filled, or some position closely allied to it.

The next step in the course of our evolution was the discovery that the class of cases that should receive the attention of the Rehabilitation Commission was largely of the class of cases annually coming before the State Compensation Board. We have from twelve to fourteen hundred cases reported monthly as being sufficiently disabled to come within our schedule. We divided the state into five districts and placed in each an Industrial center consisting of a court room where the compensation hearings are held, the offices of the Rehabilitation Commission and the factory inspection of that particular district. There are also located there the public employment offices and one of the clinics.

To this center the industrial worker comes to ascertain the extent of money compensation to which he is entitled. He comes with the injured hand, the injured back, or whatever may be the cause of his physical handicap, and goes before the administrator for an adjudication of his compensation claim. The Chief of the Industrial Clinic is also the adviser of

Fig. 1. The man pictured herewith was a victim of an industrial accident. After several months of baking and massage and after being fitted with a sacro iliac belt he was able to resume work.

the Compensation Administrator; and before the latter will give a money award, he has the man examined by the Chief of the Industrial Clinic, who advises, first, as to whether it is possible, by further operation, electricity, massage, or the use of apparatus for physical reconstruction, to return some percentage of the usefulness of the worker. If that is, in his judgment, possible, the commissioner will first insist on having the man return to the clinic and be placed under the care of the state and improved to the greatest extent possible before he will take up the subject of compensation.

After having been reconstructed and rehabilitated to the fullest extent, —and, in many instances, before the rehabilitation is undertaken — the

Commission makes a study to see what is possible for the man in the way of a return to usefulness. Visits are made to the hospital once a week to ascertain whether there are any patients in the hospital who need the advice of counsel as to their possibility of securing compensation awards, or whether it is possible to be of any welfare assistance to them. A study is made of their cases, and the men know when they are ready to come out of the hospital and face the world again in their maimed condition that they will have someone to whom they can go for counsel and assistance.

The next step is the question of placing the man, woman or child in a suitable position after he or she has been reconstructed in the best possible way. Those engaged in work on sociological lines, or on placement work, endeavor to get in contact with the industries. This, in my opinion is the one feature of the rehabilitation work which clearly places this problem within the realm of industry. It is a problem of the conservation of the human element under the operation of our various labor departments even more than under the educational regime. For conservation ultimately implies the best possible adaptation of the handicapped man with the least possible disturbance of his acquired habits, or shifting him from the industrial occupation in which he was engaged prior to his injury.

I do not know of any one thing in our industrial life which has been performed with less efficiency than the old system of hiring and firing a man looking for a position and wasting his time, when there were thousands that wanted that particular class of worker. I believe that there should be a clearing house where the men wishing to hire a particular type of worker can inquire whether a worker is listed there for that particular type of employment. That can be accomplished only if you have the confidence of the employer, and also the confidence of the labor element of the country. We believe that we have worked out a system where there is a relative degree of confidence in our work.

We have been required to work in the early hours of the day because in the early hours the largest percentage of the work of the office is accomplished. Working with the employ-

Fig. 2. Same patient as in Fig. 1 wearing sacro iliac girdle physically rehabilitated and doing laborious work.

ment officer, we become acquainted with the employers, and know better the character of openings existing in the community. This information makes the Rehabilitation Commissioner much better able to discharge his duties.

The department which is best calculated to be of direct benefit to the men is the Factory Inspection Service. From these centers radiates the work of the Factory Inspection Department in these communities; and we have made arrangements that if the Commissioner wishes to see where he can obtain a certain class of employment, he can have access to factory lists and discuss with the men the plants which can employ that type of worker. Owing to the peculiar position in which the Factory Inspector is placed, he can get a better hearing than any other man connected with the work; and some of the best placements have been made with the help of the Factory Inspector's department.

The cases frequently require a study in the care and assistance of the man who has been injured in industry. This whole problem requires first, a definition of what is a handicapped worker, a handicapped citizen. An instance which may be cited is that of a man who had fifteen hundred volts of electricity pass through his body—enough to kill several men, and there is no adequate explanation as to why he was not killed. His arm was taken off at the shoulder, his right leg was injured, and his scalp began to slough off, leaving a place the size of the hand through which the pulsating brain was exposed. The slightest blow there meant death. It

was necessary to have a silver plate made to protect his brain. He received the highest compensation allowed in New Jersey. Very much to our surprise, he came to the office one day and said: "Now what are you going to do about getting me a job?" We said we did not know that he would want to work. He said: "I am not going to go home to die. I want a job." The surgeon said that the man was liable to die at any time, even while going downstairs. We took the matter up with the Public Service Corporation, and the question of compensation in case of further injury or death while in their employ was finally adjusted.

activities showed that he had been a salesman in a tobacco plant. We were able to obtain for him a position in a tobacco plant as a salesman, and in three months he came to the clinic in an automobile owned by himself to take our representatives and assistants for a ride. It was shown that he was making more money than they were, and the firm reported that he was the most satisfactory salesman that they had ever had. These men need that particular care at their crucial moment, and this case is typical of thousands of cases.

The general scheme of our rehabilitation work is the same as in Pennsylvania. We are fortunate in having wide latitude in the administration of our affairs. The administration in Washington has been helpful in advising and directing us as to the side of the work they are most interested in; and I believe that they think it would be well if more latitude were given in the other states. As compared to Pennsylvania, we have the great advantage of being able to conduct these clinics and spend the money allowed for physical rehabilitation.

These clinics, known as ambulatory orthopedic clinics were something of an innovation and placed the state more or less in the field of medicine, creating a delicate situation, because the physicians and surgeons felt it to be the beginning of what is the bogey of all physicians—state medicine, or, it may be, compulsory health insurance. They are now convinced, however, that the object of the clinic is to supply that peculiar type of coordinated treatment which cannot be delivered by the average practitioner or the general hospital, and can

Fig. 3. Industrial accident showing amputation at the upper third of the left thigh.

After that, it was necessary to find something for him to do. They had a harness made which held the receiver of a telephone to his ear. We gave him a little instruction in the use of the switch board; and every day that man comes down town with one arm off and an injured leg and works for his allotted number of hours at twenty-five dollars a week. The man is allowing his wage to accumulate to pay for the purchase of some eight per cent bonds; so that, at the end of the four hundred weeks, he will receive enough money to be able to live for the rest of his life in comparative ease.

The most helpful angle of the Rehabilitation Commission is that intangible thing known as morale. Getting hold of themselves, men practically down and out, regain their initiative and their grasp on life. Only a few days ago, a man came to our office who was about to do away with himself. Examination of his previous

Fig. 4. Same man as shown in Fig. 3 with artificial leg attached.

Fig. 5. Same patient as in Fig. 3 in placement vocational training. He has been in continuous employment for one and one-half years.

be found only in the peculiarly specialized plant wherein the appliances for orthopedic treatment in its widest sense are found. Assuming that the average practitioner had the equipment (which he could not have, on account of the expense), he would not have the time to devote to complete rehabilitation.

#### Clinic Equipment Complete

We made a careful survey of the hospitals and found that a full equipment was in none of them. The general hospital has not the room, the equipment, the nursing facilities, the expert masseurs, or the time for this work. Some of these patients receive treatment for six months, coming every day or every other day; improvement is obtained from baking, electrical apparatus, and massage.

These clinics are equipped with x-ray machines, a full line of bakers, lamps for deep therapy, and a pathological laboratory for making blood and other tests. A room is provided for the performance of minor operations. A plaster room is equipped for the application of casts. The majority of injuries requiring rehabilitation affect the arms or the back. For the restoration of muscular strength there are provided bicycles, rings, punching bags, wheels, so that the injured men can pursue the specific exercises required. The McKenzie apparatus is available, the high frequency machine, electric vibration, are used, and within the past year we have developed a fully equipped orthopedic hospital. The workers are receiving the type of restorative treatment which originated during the Boer war as an outgrowth of the

measures utilized by Dr. Jones, of London, a bracemaker who by such devices was able to reconstruct and return to the front men who had previously been thought wholly unfit for service.

A final point to be emphasized is that the physician in charge of a rehabilitation clinic needs to be of the highest type of his profession. Nothing short of scientific precision of method will serve to restore these

men and, in the state of New Jersey, at least, it can be said that the injured worker receives a diagnosis and treatment as efficient for his type of case as it is possible to secure. Four clinics are in full operation, and a fifth is being organized. More than a thousand treatments were administered during the month of April. It requires little vision to see that the reconstructive value of such measures is inestimable.

## British Factory Hygiene Report

The Annual Report of Chief Inspector of Factories for 1921 shows that British factory hygiene continues to hold its place in the front rank. In spite of the trade depression the number of factories has increased and the number of workshops has diminished. An increase in the work of inspection has naturally followed the multiplication of rules and regulations, but the owners show a cooperative spirit with few indications of a desire merely to comply with the minimum requirements of the law.

Improvement has been made in the introduction of mechanical grinding in the cutlery trades; in the sanitary conditions in food factories; in the use of abrasive wheels containing little or no free silica; and in the use of automatic and semi-automatic machinery in the glass-blowing trade. Temperature and ventilation conditions have shown a marked improvement, and although window-cleaning is still a topic for adverse comment general lighting conditions have shown some advance.

Undesirable conditions still exist in the work of loading and unloading ships. Nearly 46 per cent of the reported septic cases had received no first-aid treatment. The employment of unskilled labor in hazardous occupations and the foolhardiness of the skilled workers caused many needless accidents. The occurrence of "brass-founder's ague" among men using the oxy-acetylene flame on galvanized plates is recorded. Aniline-black poisoning among dye workers is to be the subject of further investigations. Cases of lead poisoning are less in number and severity. It was found that the rescuers in cases of carbon monoxid poisoning often walked the patient up and down with the idea that such treatment was beneficial. The great need of rest in such cases is emphasized.

The question of hours of work and the problem of the underground work-

room in London are also discussed. In general the report shows the record of a successful year.

The South African Institute for Medical Research has published the results of Mavrogordato's study of silicosis on the Rand. This experimental study corroborates the epidemiological findings that only silica dust produces conditions comparable to those found in tuberculous silica in man, and that the chemical activity and solubility are factors of great importance while hardness and sharpness exert little influence. Autolysis and digestion in the lymph of ingesting cells seems to be inhibited by some property of silica particles. Coal dust was found to have no effect on this action once the silica is fixed but in concurrent exposure coal dust prevents this fixation.

A small outbreak of lead poisoning due to beer was reported by *The Lancet*, August 12, 1922. A local practitioner in Middlesex recognized that several of his patients were developing symptoms of lead poisoning and notified the medical officer of health. Investigation disclosed the fact that the beer was free from lead on leaving the brewery. The contamination had occurred in certain public-houses that used for storage purposes large iron tanks lined with a lead glaze.

According to Dr. Arthur L. Murray, surgeon of the United States Bureau of Mines, the monetary losses due to accidents and contagious diseases in the coal mining industry of the state of Utah average close to a million dollars per year. With vaccination and typhoid inoculation so simple, Dr. Murray considers loss from either of these diseases inexcusable. Ascertaining and eliminating the sources of infection of the latter disease is also possible.

# Eye Symptomatology in Occupational Diseases

## Chemical Factors Are Usually Responsible for the Eye Disorders of Industrial Origin

By DONALD J. LYLE, M.D., AND CAREY P. McCORD, M.D., CINCINNATI, OHIO.

THE eyes of a high percentage of industrial workers have proved from extensive investigation to be defective. The proportion thus involved has varied from fifty to ninety per cent as reported from widely different types of industry. As a result of publicity subsequent to these striking findings a conception has become prevalent that industry itself has caused these defects. To those better acquainted with the problem, it is patent that many persons in industry exhibiting poor eyes possessed the same defects actual or potential, prior to their entry into industry. In other words, any group of persons without any industrial experience and without known exposure to any conditions harmful to the eyes will likewise reveal on examination much impairment of the eyes and eyesight. A large portion of the responsibility for the causation of poor eyes may thus be shifted from the shoulders of industry.

But associated with industry there exist diverse conditions of work conducive both to the initiation and the aggravation of eye defects. The types of work particularly linked with eye sight impairment or eye injuries are those involving: (1) dust, abrasives, and flying particles; (2) splashing metals; (3) gases, fumes, and irritating chemicals; (4) glare; (5) radiant energy, chemical, and heat rays; (6) defective posture; (7) poor lighting. The items of this group are commonly regarded only as "eye injury hazards." These same conditions, however, may be considered the sources of many "eye occupational diseases," and any attempt to demarcate eye injuries from eye occupational diseases does nothing more than erect an artificial barrier between two similar sets of affections. It may with propriety be held that every eye impairment attributable to industry is in a sense an occupational disease.

The purpose of this paper is to describe a number of occupational affections of the eye that do not present the ordinary characteristics of the swiftly produced injury; that may develop insidiously; that commonly are not linked by the worker with his occupation; that may be accorded by the physician a diagnosis that fails prop-

erly to associate the malady with the patient's job as the producing factor.

Nystagmus may be found among those workers who year in and year out subject their eyes to abnormal and unaccustomed motions. The miner develops a nystagmus due to constant, imperfect fixation of his eyes on poorly illuminated objects; the chauffeur acquires nystagmus by the constant watching of traffic without complete fixation; the compositor by watching the type which he is setting; the paper hanger and painter by following their brushes, the position of the body often thrown out of a vertical position, thus causing more strain on the visual apparatus. For like reasons, locomotive engineers, draughtsmen, jewelers, typists, textile workers, and others may acquire a nystagmus.

### Occupational Nystagmus

The short, rapid, continuous involuntary movements of the eyeball characteristic of nystagmus may be induced by occupational causes affecting the eyes through the central nervous system or from some extraneous cause. Nystagmus develops in a coal miner affected with carbon monoxide poisoning, the eyes responding to irritation or disease in the central nervous system. When, however, nystagmus in a coal miner is due to poor illumination, or faulty visual fixation of objects on the black coal face, the effect is produced by direct action on the ocular apparatus. Young children living in dark houses suffer from the same form of nystagmus owing to the defective development of the fixation reflexes.

A variety of occupations produce practically the same symptom complex. Miner's nystagmus, the best known and the most thoroughly investigated example of occupational nystagmus, occurs in from 3 to 25 per cent of coal miners. It usually appears between the ages of thirty-five and forty years among men who have engaged in mining for many years. Coal miners are much more prone to this affection than other underground workers, a fact which is attributed by the Miner's Nystagmus Committee of the British Medical Research Council

to the additional blackness from the coal face. Of all cases among underground workers, 81.5 per cent occur among persons at the coal face.

Predisposing factors in miner's nystagmus are: (1) errors of refraction; the percentage of affected persons presenting errors of refraction is between seventy-five and eighty-five. Persons with astigmatic errors are more seriously affected; (2) unbalanced extrinsic ocular musculature; and (3) neurotic tendencies.

The factors which excite or produce the condition are (1) poor lighting. The prime factor is poor illumination which includes low lumen power, glare, and unrelieved, black coal face. Nystagmus is rare in metal mines, in which good illumination exists, and is much less frequent in coal mines with adequate illumination, with white-washing, etc. (2) Working where an upright position cannot be maintained. (3) Lowered physical state (including injuries.)

The most severe and most common subjective symptoms are: headaches and dizziness; dancing and dazzling of objects, especially lights; failure of sight, especially at night (if above ground); photophobia; general fatigue. The objective symptoms include: (1) rotatory, lateral indefinite, or mixed movements of the eyeball, their frequency being in the order mentioned and their severity and duration indicating the degree of lack of coordination; (2) general condition of depression; (3) increased nervous irritability; (4) blepharospasm; (5) spasms of brow, head, neck, and sometimes shoulders.

Treatment involves a discontinuance of work at coal face, rest, correction of refractive errors, general building up of patient both physically and mentally. Less than 1 per cent of cases are permanently affected. Of the remainder all physical signs usually disappear within two years after the man has left coal face work. Many clear up within a much shorter time. In those cases permanently or semi-permanently affected, marked psychic disturbances have usually been concurrent with or have preceded the eye condition. Preventive measures need to include (1) Corre-

tion of refractive errors and muscular instability. (2) Adequate illumination, without glare. (3) White-washing of extensive portions of mine (passageways, timbers, etc.). (4) Arrangement of working hours so that there may be opportunity for recreation in daylight. (5) Thorough medical supervision, and the maintenance of high physical standards among workers. (6) Proper mine sanitation, particularly with reference to humidity, cooling power of air, absence of carbon monoxid, etc.

### Carbon Monoxid Poisoning

Carbon monoxid poisoning is the commonest of all occupational diseases. This condition is found as acute, chronic, or delayed poisoning. It is to be recognized that serious and lasting harm to various systems and organs of the body may follow exposure to carbon monoxid. A small percentage of persons thus poisoned present eye involvement. It is noteworthy that the eye changes show little constancy. The list of eye manifestations definitely associated with carbon monoxid poisoning includes the following: color blindness, contracted visual fields, diplopia, scotoma, hippus, impairment of pupillary light reflexes, irregular pupils, unequal pupils, diminished vision, engorgement of retinal vessels, retinal exudate, sectional blanching of optic discs, edema of optic discs, optic neuritis, optic nerve atrophy, and complete ophthalmoplegia, with marked protrusion of the eyeballs.

A typical case of carbon monoxid with temporary blindness is reported by Abelsdorff in a worker who was exposed to the fumes from a charcoal stove. After about two days he suffered from headache, malaise, dizziness, vomiting; on the fourth day, diminished vision appeared and on the fifth day he could scarcely recognize large objects. Physical examinations of the eyes were negative, except for a slight, horizontal nystagmus. At this time no carbon-monoxid-hemoglobin was found in the blood. On the sixth day, vision in right eye, hand movements at one meter; field of vision contracted almost to the fixation point; left eye practically in same condition; color blindness existed in both eyes. Eye movements were normal except that the right eye was sluggish in upward movement. Fundi were normal. At the end of one week, and without medication, vision was, right 6/20, left 6/25. The fields were concentrically contracted, no scotomata; color blindness remained in part; paresis of the left inferior rec-

tus. At the end of three weeks, pupils were clear, vision normal, fields were normal but paresis persisted.

Carbon bisulphid is commonly taken into the body through the lungs, after exposure to its vapors. In chronic cases, the vision is gradually lessened beginning with a retino-bulbar neuritis and progressing slowly to nerve atrophy. The prognosis is never good. In advanced cases, vision is seldom recovered.

Both soluble and insoluble arsenic preparations are capable of producing external and internal injury of the eyes. More frequently the manifestations are late, due to slow absorption of a small amount of arsenic which has entered the system through the alimentary and respiratory tracts. The chief complaints from the patient center about (1) pain in the eye, with itching, burning, and irritation; (2) painful vision, blepharospasm, lachrymation, and photophobia; and (3) loss of vision, as nerve becomes affected. The most constant eye findings from systemic involvement are peripheral neuritis, optic atrophy with amblyopia, contracted fields, and scotoma. Less frequently opacities in the vitreous are noted. Both eyes are usually affected, often unequally. In animal experiments, a degeneration in the medullary sheaths of the optic nerve fibers has been found. The action of arsenic on the external eye leads to edema and pigmentation of the eyelids, chemosis, and sometimes hemorrhage of the conjunctiva. The conjunctivitis may arise either from direct or systemic poisoning.

### Ocular Lead Poisoning

The eyes are involved in about 1.2 per cent of all lead cases. Although the eyes may be the only source of complaint, careful examination will ordinarily lead to evidence of systemic lead poisoning. Ocular manifestations of lead poisoning vary widely. The symptoms and findings may involve any or all parts of the eyes. There is little reason to believe that the harm to the eyes is traceable to lead directly entering the eyes. The usual modes of entrance through the alimentary tract and the respiratory system are more acceptable as sources of the lead reaching the eyes. No form of lead is known to have any special predilection for the eyes. Usually the patient complains of headache, vertigo, blurred vision, constriction of the visual field, central color scotoma, perverted color vision, or diplopia. The physical findings include any or all of the following symptoms: ptosis, conjunctivitis, paralysis of the

extrinsic ocular muscle, especially those enervated by the third nerve, retinal edema, neuro-retinitis, retinitis-saturnine, optic neuritis, and optic atrophy. The damage from lead may be transitory, due to an ischemia, or permanent through the action on the optic tract or to perivasculitis. Since lead may induce a chronic nephritis, some difficulty may arise in differentiating between ocular lead poisoning and albuminuric retinitis.

No measures of prevention or treatment apply specifically to the eyes. If systemic lead poisoning is prevented no instance of ocular lead poisoning will appear.

### Methyl Alcohol

Although the greater number of cases of wood alcohol blindness has in the last few years developed from the use of this poison internally, a considerable number still arise as the result of intoxication following exposure to wood alcohol used for industrial purposes. Less methyl alcohol is utilized in industry at the present time than was true a decade past. About twenty years ago, after many deaths and much blindness from methylated spirits in industry, the section of ophthalmology of the American Medical Association petitioned Congress to permit the production of a commercial ethyl alcohol that would undersell the dangerous methyl alcohol (passed June 7, 1906). This cheaper denatured alcohol is an acceptable substitute for the harmful wood alcohol except in a few trade processes wherein the use of methyl alcohol is requisite.

Methyl alcohol may act as an acute or chronic poison, the chronic form being most insidious and many times not easily diagnosed. In either case the ocular symptoms arise as a part of the general systemic poisoning. The affected worker complains of decreased vision and lessened visual fields. Upon examination there is found, in an early case a retrobulbar neuritis, or pallor of the discs with constricted retinal vessels. Atrophy of the optic nerve is a later development. Opinion is that the chronic poisoning first destroys the axis-cylinders, later attacking and destroying the ganglion cells. Blindness is reported to develop in 6 per cent of all persons poisoned by methyl alcohol. The chances for restoration of vision are very poor. Most of those affected remain permanently blind.

To avoid wood alcohol poisoning, denatured ethyl alcohol should be employed wherever possible; where the substitution is not possible, wood alcohol should be utilized in "closed cir-

cuit," wherever compatible with the trade process. Adequate exhaust, together with good factory ventilation is essential. At all times, workers should be acquainted with the harmful properties of wood alcohol and the conditions under which poisoning may arise.

### Anilin

Anilin and many of its related chemical compounds are capable of inducing eye lesions. The eyes may be affected externally by anilin vapors, especially hot vapors. For the most part, however, the eyes are harmed by anilin which is absorbed through the skin or taken into the body through the respiratory or alimentary tracts. Acute anilin poisoning is likely to involve the eyes by external irritation with a temporary blurring of vision. On examination of workers long exposed to anilin, the external eye may be found to be uniformly pigmented. The corneal epithelium is roughened and pigmented. A conjunctivitis with ciliary injections is frequently encountered. In the more advanced case, scotoma and amblyopia are to be found. Retinoneuritis has been observed.

Prognosis in such cases is good provided the source of intoxication is removed.

### Occupational Cataracts

Slow developing cataracts frequently exist among workers whose occupations involve continual exposure to intense light and heat. These cataracts are especially associated with workers in molten glass; but are known to arise in such other industries as chain making, smelting, tinplate making, welding, acetylene and oxyhydrogen cutting. Both heat and light are factors in causation of occupational cataracts. Intense light without pronounced heat will produce opacity of the lens in experimental animals. The emanations from molten glass are rich in heat rays and poor in chemical rays. Concentration of the aqueous humor, due to constant evaporation on the surface of the cornea, may be an etiological factor. The period of cataract formation is long. For many years a progressive opacity of the lens, usually in both eyes, goes on without any knowledge of the victim. Ophthalmoscopic examinations may show distinct lens involvement long before any complaint of lessened vision. In the glass industry the left side of the blowers' face is held closer to the oven and often the left eye is involved before the right.

The cataracts are posterior-polar or cortical, varying in size and shape, some being round, some rosette-shaped and some irregular in form. It has been suggested that the reason for the opacity being only in the visual path is that the iris pigment and blood vessels protect the periphery of the lens from the harmful rays. The damage appears to be limited to the lens. A few reports refer to disturbances of the retinal pigment.

Other than the gradual loss of vision, no subjective symptoms are complained of by exposed workers. During the formative period no complaint is made and usually not until well established opacity exists are these conditions brought to the attention of the ophthalmologist. Often the vision is reduced to one-tenth normal before medical advices are sought.

Provided no other lesions or complications interfere, the operative risks in occupational cataract are good. This is contrary to the usual posterior or cortical cataract. As a rule, on account of loss of all accommodation, operated employees cannot resume their former work.

Protection against occupational cat-

aract is to be found through the continuous use, during the exposed period, of goggles that absorb or disperse both the heat and chemical rays. Such goggles lend themselves to use containing a plain glass or a glass correcting the workman's refractive error. Great difficulty in securing protection from the development of occupational cataract arises from the disinclination of workers to wear these protective glasses continuously through the long period in which cataracts are insidiously developing.

The participation of the eyes in chronic occupational disease is by no means limited to the foregoing conditions. To this group may with propriety be added many such lesions as immobile pupils, nystagmus, corneal opacities, following long exposure to benzene; paralysis of ocular muscles resulting from picric acid; keratitis found among harvesters; retinal and papillary edema followed by fatty degeneration presented by workers in phosphorus; divers chronic eye lesions arising among workers in pharmaceuticals; and amblyopia occurring among tea tasters and tobacco workers.

## Kinesthetic Knowledge

MUSCULAR skill has a much higher intellectual value than is usually assigned to it. Bodily skill—the ability to deal with the world by means of one's muscles—is no mean achievement, and carries with it a specific and unique kinesthetic knowledge. T. H. Pear in a recent issue of the *British Journal of Psychology* discusses at some length the structure of knowledge which is the unique possession of persons of muscular sense only, such as that arranged and synthesized by Helen Keller. Complicated behavior can go on without the slightest trace of visual memory. Coordinations of bodily movements are achieved with difficulty, and notwithstanding the great usefulness of physical training in the general education, there is almost a complete lack of descriptive words to express kinesthetic experiences.

Pear suggests that a hundred simple, elementary, and typical attitudes of the body and limbs be developed from existing manuals of drill and physical training and eurythmic exercises as fundamentals, and that such exercises as fencing, golfing, cricket, and skating be analyzed and their definite "stances" be learned and named, so that they could be asso-

ciated with definite kinesthetic experience. Motion study in this connection is very important.

It is because the motiles as compared with the socially established visiles and audiles seldom get fair play that the intellectual value of motor coordinations is little appreciated. How closely the doctrine of "conscious attitude" advocated by Pear is related to the left wing of behavioristic psychology it is difficult to say, but it is safe to say that greater precision and more rapid reaction become possible as visual and auditory imagery are supplemented by the so-called muscular sense. Even the heaviest muscular effort has its resulting coordinations of real intellectual value, which accounts, to this psychologist, at least, for the direct thought and fearless conclusions of many of our typical laborers.

The Safety Institute of America has inaugurated a safety film service for members and others particularly interested according to announcement from headquarters in New York. The service was made possible by a gift from the department of safety, sanitation, and welfare of the United States Steel Corporation.

# The Effects of High Temperatures and Humidities\*

## Physiological Basis of Modern Ventilation and Present Methods of Research

BY W. J. McCONNELL, B.S., M.D., PASSED ASSISTANT SURGEON (RESERVE), U. S. PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

IT is a fact daily becoming more impressive, that exposure of workers to high temperatures and humidities is one of the most serious of the health hazards incident to occupation in many industrial plants. Measures designed to obviate this hazard are of interest, not only to industrial physicians, but to those interested in the physical sciences as well. The problem is essentially one of ventilation, and only with the solution of its perplexing questions can we hope to mitigate the heat hazard.

Although nearly a century has passed since the first commission on ventilation, a group of Englishmen, began to study this problem, some doubt still attaches to the question as to when a room is properly ventilated, and what amount of air may be considered necessary adequately to ventilate an enclosed space.

With the introduction of steam, and the growth of industry in general, the problem of ventilation has become more complex. Today, the effects of working in excessive heat and moisture must be dealt with, and the different methods of measuring these effects must be studied.

In the light of the more recent investigations, we have changed our methods of determining the fitness of air and, in fact, have come to look upon the entire problem from a different point of view.

Formerly the physical and chemical method was used almost entirely to determine the fitness of air, and a chemical analysis of the air was considered very important, together with the number of cubic feet of air supplied per hour. The air problem was considered a problem of chemistry; and ventilation, one of supplying chemically pure, and removing chemically impure air.

The present conception is that living beings constantly produce and give off to the atmosphere their excess of heat. This heat is carried away partly through the lungs, in the expired air; but chiefly through the skin, by radiation, conduction and

the evaporation of perspiration. An atmosphere which is neither too hot nor too humid to insure this heat removal must surround the body. In many industrial plants there exists an atmosphere which is too humid for the proper dissipation of body heat; and the normal physiological functions of the body are interfered with. Many recent investigations have been made to ascertain just what physiological changes take place; and if any criticism can be made of the work so far completed, it is that the investigators have too frequently studied the more extreme conditions and overlooked some of the less apparent, but equally important symptoms of slightly inhibited or slightly accelerated reactions of a physiological nature. Their experiments were, likewise, continued for too brief a time; and their observations were limited to only a few of the more easily measured bodily functions, such as body temperature, respiration, pulse and blood pressure.

### Physiological Problems

Until we know all the physiological processes interfered with or altered by the effects of high temperatures and humidities, we must consider a greater number of bodily functions; because frequently it is the unexpected thing that happens. As an example of this, it is interesting to note that Bloch, in his study of fatigue as experienced in different parts of the body, in different trades, found that the blacksmith who had been striking iron did not complain of his arms and shoulders, as might have been expected; but of his back and loins. The recruit, after a long march, although not carrying a haversack, complained of pain in the nape of his neck; the shoemaker, who hammered tacks into the soles of boots, was fatigued in his abdominal muscles; the boatman, as the result of prolonged rowing, complained of the insteps of his feet; while the artist complained of numbness of the muscles of the left hand, as a consequence of holding his palette tightly.

The United States Public Health Service, cooperating with the Bureau

of Mines and the Society of Heating and Ventilating Engineers, is at present engaged in a study of the relative importance and correct correlation of the many individual factors concerned in the problem of ventilation, and the physiological effects observed under different conditions of temperature, humidity and air motion.

It is realized that thorough results may be expected from cooperative experiments in which experts, each in his own field of work, attack the problem from their point of view under leadership. No matter how skilfully a scientist may pursue his studies, it is evident that greater advances can be made more rapidly and more certainly by a concerted attack upon a problem by congenial cooperation among men of different scientific training.

The equipment of the Bureau of Mines for this kind of research work is extraordinarily excellent. A psychrometric room eighteen feet square, with a ceiling height of ten feet, lined on all sides with four inches of cork board, and designed automatically to maintain air conditions at a desired temperature and humidity, has been equipped for this purpose. The air conditions are controlled by apparatus outside of the chamber, and entirely separated from it. The air, heated to a desired temperature and saturated with moisture to a desired degree, enters the chamber through a fourteen-inch circular inlet, and is propelled by a blower connected to a five-horsepower, sixty-cycle motor, which is capable of handling one thousand cubic feet of air per minute. The room is divided into two chambers, separately controlled; so that it is possible to determine the sensitiveness of the body to slight changes in temperature and humidity by having the subjects pass from one chamber, of a given temperature and humidity, to another, slightly different.

A very comprehensive program is at present being carried out, which includes a quantitative study of a considerable number of bodily functions. As probably no living organism of any kind can endure great variations

\*Condensed from a paper presented before the Fifteenth Conference of Industrial Physicians and Surgeons, Harrisburg, Pa., May 25, 1922.

of external temperature, and, at the same time, retain its physiological efficiency, as well as can man, human subjects are used in the experiments, under accurately controlled air conditions.

At half hour intervals, the pulse rate, respiration rate, blood pressure and body temperature are recorded. The mouth temperature is registered by the clinical thermometer, while the rectal and surface temperatures are recorded by means of thermocouples. Before entering the experimental chamber, the subjects remain for two hours in a room kept within a known range of temperature and humidity; and records of pulse rate, respiration rate and temperature are made, in order to learn the condition of the subject before entering the chamber on the day of the experiment. On entering and leaving the chamber, the subject is weighed on scales which register within a quarter of an ounce.

The subjects remain in the chamber for a period of three hours, during which time, in addition to the above

measurements, metabolism, by the indirect method, and hemoglobin determinations are made. It is also contemplated to make lactic-acid, blood sugar, and other examinations of the blood; such as bloodcounts, hydrogen-ion concentration of the plasma, a determination of the agglutinating and hemolyzing power of the blood, the resistance of the erythrocytes to laking by hypotonic salt-solution, the concentration of chlorides in the corpuscles, and that of bicarbonate in the plasma. Some quantitative studies will also be made of the urine and sweat of the subjects exposed in the chamber.

#### Standards of Measurement

Our experiments, so far, have been too few in number to arrive at any conclusions pertaining to the physiological reactions to different conditions; and I can only, at this time, emphasize the importance of determining the physiological reactions to a controlled environment as a measurement of the harmful effects of heat

and humidity. Experience has taught that we cannot depend entirely upon our feelings of discomfort as a standard of measurement; because there is a certain adaptation of the sense organs to an unchanging environment, and because people differ in their sense reactions. In conclusion, I wish to state that, as important as laboratory experimentation along these lines is, still the results are not always conclusive, and may be expected to serve only as a guide to devising means to provide human beings with air fitted for their use. Industry supplies, for the study of the clinical side of this problem, great opportunities, which are today hardly sufficiently appreciated. Industrial physicians can assist very materially in the ultimate solution of this, and similar problems, by reporting their observations on workers exposed to the various industrial conditions that they find; and in this way, cooperate with their laboratory colleagues. By such cooperation, the solution of industrial problems will be simplified and expedited.

## Drug Misconceptions As Applied to Surgery\*

THE surgeon as well as the internist sees much harm resulting from popular misconceptions in the use of drugs. Two such misconceptions frequently encountered are the belief that (1) iodine is an innocuous panacea, and (2) carbolyzed vaselin as obtained at any drug store is a harmless antiseptic and very superior to plain vaselin, which would not kill any germs.

#### Tincture of Iodine

The tincture of iodine of the United States Pharmacopeia is a 7 per cent solution of iodine and alcohol. As such, when applied in a thin layer to the skin, it acts as a very efficient disinfectant and a mild irritant. In the case of the average individual it will not cause a dermatitis when applied in small amounts. The popular misconception consists in this, that if a little or 7 per cent solution of iodine is a good disinfectant or a mild counter-irritant, a larger quantity will act much better and more quickly, so that instead of applying the iodine in a thin even layer it is painted over and over again. Often to make matters worse a non-permeable dressing is applied over the iodinated area thus preventing any possible loss of iodine through

volatilization. A frequent result of such treatment is that the patient presents a severely blistered skin area surrounding an insignificant scratch.

Another misconception is that iodine will disinfect by absorption. Although iodine is absorbed and may have a slight power as a disinfectant in this way, it is in the highest degree erroneous to hold that bacteria in the deeper tissues or even the deepest skin layers will be affected by iodine applied externally. Iodine acts as a disinfectant where it comes in actual contact, where it stings, but a daub of iodine on a pin prick will not affect the bacteria carried down into the deeper tissues. Its counter irritant effect may increase the blood volume in the area and thus aid in preventing infection, but not more so than a simple hot wet dressing.

For bruises, sprains, and contusions the only good that an application of tincture of iodine could possibly do would be on account of its irritant properties, and here again heat would cause a much greater vaso-dilatation if that is desired. Due to the prevalent idea that tincture of iodine is good for bruises, the surgeon is often called upon to treat, not the bruise, but the iodine burn. "Paint it with iodine and mark him duly," was supposed to be the medical department's slogan during the war. If iodine is used

for conditions other than those absolutely indicated, it was at least applied in small amounts and usually left uncovered.

#### Carbolyzed Vaselin

Carbolyzed vaselin as commonly dispensed and used is a most dangerous drug. Its sale ought to be restricted in the same manner as the sale of pure carbolic acid. When properly made, carbolyzed vaselin is not dangerous, for it is a weak and stable solution of carbolic acid in petrolatum. To make carbolyzed vaselin properly the pure crystals of carbolic acid must be dissolved in the vaselin. This is a slow and laborious process. Many drug stores make their carbolyzed vaselin out of solutions of carbolic acid. This, however, forms an unstable compound. The carbolic acid solution is not held in suspension by the petrolatum but is gradually separated.

The patient using a jar of old carbolyzed vaselin may get a portion of plain vaselin or may get a portion of vaselin containing a highly concentrated amount of carbolic acid. When this is smeared on the wounded area and a heavy dressing placed on top of it a very serious injury may result. Such an injury may vary from the superficial carbolic burn to an actual gangrene which may cause an ex-

\*The seventh of a series of articles on "Popular Medical Misconceptions" beginning with the March issue of THE NATION'S HEALTH.

tensive tissue destruction and call for radical surgical interference. It is not an infrequent occurrence in the dispensary to see a serious and permanent injury resulting from the application of carbolyzed vaselin to an insignificant scratch or cut. The medical profession itself is not sufficiently impressed with the dangers of ordinary carbolic vaselin. If physicians

realized the likelihood of their patients obtaining an unstable solution and the dire possibilities which may follow, carbolyzed vaselin would never be prescribed. Its possibilities for danger are such that the sale of carbolyzed vaselin should be forbidden except with the same restrictions which govern the sale of pure carbolic acid, cyanids, and other deadly poisons.

## National Safety Council

THE annual meeting of the National Safety Council, held in Detroit, August 28 to September 3, indicates a greater broadening of their field of effort than their original purpose of preventing accidents in industry. The interest of the community in accident rates and the part of the citizenry in accident prevention were well emphasized in tabulations of accidents which are presented in the September issue of *THE NATION'S HEALTH*. Vehicular accidents in fifty American cities were analyzed by Ambrose Ryder and H. P. Stellwagen of the National Bureau of Casualty and Surety Underwriters. Cause enough appears for the present concentration on this matter and for the finding of funds for prevention, education in the rules of the road, and special protective devices.

Dr. Nelson M. Black offered a very practical exposition of the subject of eyestrain in industrial occupations, dividing cases of eyestrain into two groups, (1) those under proper illumination which result from standard vision due to congenital conditions, disharmonious muscular action, or defect or disease in the eye itself; and (2) those resulting from improper or inefficient illumination. The place of visual tests in routine physical examination received attention as well as the subject of proper adaptation of the worker to the job. Once the basis of intelligent placement is understood, the problem of making working conditions right can proceed intelligently. Carbon monoxid poisoning as a health menace was discussed by Yandell Henderson.

The platform of the Council for 1923 is embodied in the following resolutions:

WHEREAS, the 80,000 accidental deaths and millions of injuries occurring each year on our streets, in our industries, in homes and elsewhere are a blot on American civilization and the cause of untold suffering and sorrow, and

WHEREAS, the direct economic cost of industrial accidents alone exceeds one billion dollars annually, and

WHEREAS, experience has demonstrated that at least 75 per cent of industrial accidents are preventable and that approximately an equal reduction is possible as regards public accidents, therefore be it

RESOLVED: That the National Safety Council in its Eleventh Annual Congress in Detroit assembled advocates:

(1) The safeguarding of all dangerous machinery and places according to standard methods of proved value;

(2) The development of industrial equipment and processes along lines of inherent safety for the double purpose of eliminating accident hazards and increasing production efficiency;

(3) The education of all workmen and their supervisors in safe methods and habits of work;

(4) The training in safety of all school children, as well as students in colleges and universities, both for their own protection and as an object lesson in good citizenship;

(5) The adoption and strict enforcement of uniform, practicable laws and ordinances for the safeguarding of vehicular traffic and the protection of the multitude of law abiding drivers and pedestrians against the thoughtlessness and recklessness of the few; and

(6) The mobilization of all community forces through state and city safety councils for securing these ends through the overwhelming force of enlightened public opinion.

Officers for 1922-23 were elected as follows: Marcus A. Dow, New York Central Lines, New York City, president; C. B. Auel, Westinghouse Electric Co., East Pittsburgh, Pa., vice president in charge of industrial safety; David Van Schaack, Aetna Life Insurance Company, Hartford, Conn., vice president in charge of public safety; George T. Fonda, Fonda, Tolsted, Inc., Washington, D. C., vice president in charge of sectional activities; L. A. DeBlois, Delaware Safety Council, Wilmington, Del., vice president in charge of local councils; Homer Neisz, Commonwealth Edison Company, Chicago, treasurer and chairman of finance committee; W. H. Cameron, National Safety Council, Chicago, managing director and secretary.

## Research from the Business Man's Standpoint

Industrial research is out of balance, according to Edward P. Hyde in the current issue of *The Chemical Age*. Some industries which might annually spend millions for research actually expend a mere pittance, while other concerns provide extensive laboratories and elaborate facilities for research. Five different avenues of research in American industry have recently been tabulated and discussed by A. P. Fleming as a monograph of the Department of Scientific and Industrial Research of the British Government: (1) Research applied to the elimination of manufacturing troubles; (2) researches having some new and specific object in view; (3) researches in pure science with no specific commercial application in view; (4) research applied to public service; and (5) research which is undertaken for the purpose of establishing standard methods of testing and specification connected with the purchase of raw material.

The research work now under way may roughly be divided into that undertaken in the works laboratory and the fundamental industrial research primarily devoted to the development of entirely new products, and the purely scientific research, but in fields out of which the industrial development of the future may be expected to come. A small fixed sum year by year may wisely be devoted to research of this kind, especially in those branches of industry which are in the nature of a monopoly.

There is an increasing tendency to regard the study of the needs of the consumer as quite as important as to study the manufacturing end, for industrial success depends upon the marketing of the commodity best suited to the needs of the consumer. A steel manufacturer who produced materials regardless of the demands of the engineer would meet with small success in selling his output. In the standardization of products the spirit of research might wisely prevail.

Estimates of the amount of money to apportion to research vary exceedingly. It depends to a great degree upon the foresight and judgment in initiating and organizing the research program. Business expansion and development depends largely upon the success which attends the effort to sell research to business. The research worker must utilize the advantage of prepared statistical record of the part played by research.

# Recent Compensation Decisions

By DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

**A**N employer is liable for all legitimate consequences following an accident including unskillfulness or error of judgment of the physician furnished under the Compensation Act according to the Supreme Court of Oklahoma, May 2, 1922.

The plaintiff while in the employ of the defendant was engaged in painting a tank belonging to the defendant, and, while so engaged, fell from a scaffold on which he was working, resulting in injuries to his left shoulder. After sustaining the injury he was placed in a hospital. Compensation was paid and settlement made. Later action was brought seeking damages resulting from the negligence of the physician employed to exercise reasonable and ordinary care in examining the injured shoulder, failure to ascertain the extent of the injury and failure to properly set or relocate the joints of the shoulder, causing as a result a total loss of his left arm and shoulder, and causing paralysis.

It was claimed that injuries resulting from the negligent and unskilled treatment by a physician furnished by an employer under the Compensation Law do not "arise out of and in the course of employment" or "naturally and unavoidably result" from the original injury. Further, it being a mandatory duty of the employer to furnish medical and surgical aid, the physician becomes the agent or servant of the employer and the rule of *respondet superior* applies, and the employer is therefore liable to the employee for injuries, by reason of the maltreatment or negligence of the physician, and that the employee's only remedy would be by action in the ordinary constituted courts, and not before the State Industrial Commission, as the latter tribunal would be without jurisdiction. In the opinion of the court, the Compensation Law "requires that every employer engaged in conducting any of the enterprises therein mentioned, which are declared to be hazardous, shall provide as required by the act, compensation according to the schedule of the disability of his employees, resulting from an accidental injury sustained by the employees arising out of and in the course of their employment. The lia-

bility prescribed is made exclusive except where the employee fails to secure the payment of compensation . . . and upon the failure of the employer to comply with the provision of the act, the injured employee may elect either to file his claim with the Industrial Commission, or he may sue in the court having jurisdiction of the subject matter . . . But, when the employer has complied with the act on his part, then the jurisdiction of an action to recover damages for the personal injuries suffered by the employee, not resulting in death, is exclusively before the State Industrial Commission."—*Brown v. Sinclair Refining Co.*, 206 Pac. 1042,

**I**F death can be traced directly to the accident an employer can be held liable for compensation for an employee's death by disease under the Workmen's Compensation Act the Supreme Judicial Court of Maine held April 12, 1922.

The Supreme Court, it has been held, is bound by the Industrial Accident Commission's finding of fact if there is no fraud and if there is any legal evidence supporting the findings. The facts will be given briefly. It seems that the lumber mill in which Mr. Ballou was working burned November 17, 1919. In escaping from the building he was burned quite badly. "For several days after the fire his tongue was so badly swollen because of the burns he could not speak. He was unable to eat solid foods for several weeks after the fire. He developed a severe cough immediately after the fire and when coughing he raised a brownish sputum. This continued from the day of the fire until the day of his death."

In the opinion of the court, "if the death can be traced, even though the paths of evidence be devious, directly to the accident and as a result of the injuries there received, it will undoubtedly be conceded that collateral issues of law or fact become immaterial, because, if the death can be so traced, it brings the case, regardless of the facts, within the purview of the statute. . . . The evidence, if believed, tends to show a causal relation between the injuries and the death; and the credibility of the evidence under our statute and decisions is absolutely within the judgment and

decision of the commission or its chairman. If the appellate court finds any legal evidence in the record that supports the decision, it has fulfilled its line of inquiry in that regard.—*Ballou's Case*, 116 A. 591.

**T**HE plaintiff in the case received some slight bruises on his chest when the team he was driving fell over the edge of a bridge and precipitated him into the water and wetted him. He worked all that day until about ten that night, October 1, 1920. The following day he remained at home and called a doctor who treated him for a cold. October 6 he returned to work in a normal condition by the physician's statement. He remained at work for twenty-two days when he again called the doctor who found a pain in his chest, bronchitis, and a slight pleurisy. The illness grew worse and November 11 he died from bronchial pneumonia. Claim for compensation was filed on the ground that death by pneumonia was attributable to the accident on October 1. The referee allowed his claim, which was confirmed by the Compensation Board and the Court of Common Pleas. The Supreme court of Pennsylvania in passing on the situation March 6, 1922, says that the testimony did not support the conclusion that the pneumonia was traceable back to the accident as a natural result therefrom.

Here all that appears is that the injuries were "indirectly responsible" for the pneumonia. This amounts to no more than saying it "might have resulted," which we held in the Fink cases, is not sufficient. In cases such as this, there must be a probable, direct relation between the injury and the disease, resulting in death, otherwise liability would be fixed by surmise. No such direct relation appears by the record before us. Judgment of the court below was renewed.—*Morgan v. Philadelphia & Reading Coal & Iron Co.*, 116 A. 891.

**A**N employee, while engaged in heavy work requiring him to hold heavy hangers above his head, had an attack of acute dilatation of the heart and died within a short time. The Supreme Court of Michigan, March 30, 1922, overruled the objection that there was no accident in the sense of a fortuitous, unforeseen mishap, and supported the Compensation award. Interesting implications are suggested as to possible reductions in risks of this kind through vocational alignment and competent medical counsel.—*Helder v. Luce Furniture Co.*, 187 N.W. 263.

# Elimination of Organic Odors

THE problem of eliminating industrial organic odors has been solved by Drs. Yandell Henderson and Howard W. Haggard of the Laboratory of Applied Psychology, Yale University, who have devised an apparatus whereby gaseous emanations are treated with chlorine thereby rendering them odorless. Their report is published in the *Journal of Industrial and Engineering Chemistry*. This method is much less expensive and less ponderous than the

Apparatus for control of the chlorine injected into vapor-carrying odors at Municipal Garbage Plant, New Bedford, Mass.

other method which required that the material itself be treated with some deodorant. To obtain the best results, however, the chlorine must be adjusted with considerable quantitative accuracy.

The use of chlorine has the advantage that it is already in use for the control of city water supplies, and apparatus for the control and precise adjustment of the flow of gas is manufactured and already widely used. This can be readily adapted to the chlorination of air. This method makes possible a great economy in the disposal of the garbage of a large city.

"The total amount of odoriferous substance" say the authors, "is distributed over many square miles and even when strong and offensive is in absolute amount very small, perhaps only a few grams, or at most only a few pounds or kilograms. Therefore, a process which would effect the mixture with the odoriferous substance with some deodorant agent such as

chlorine need use only a correspondingly small amount of this agent. This would give relief to the great number who live within reach of the odor."

The method of chlorination by gaseous emanations follows: The material should be dried, digested, or aerated in some closed space from which all the odorous gaseous emanations may be drawn off in a current of air through a duct. The flue from the dryer leads to the chlorinating chamber or duct, the vents from the digestors after passing through condensers are likewise carried to the chlorinating chamber. If material is turned or aerated on the floor or pressed or otherwise treated, the vapors are drawn off through an opening usually high on the walls or in the ceiling. A fan draws the contaminated air and drives it through a chamber or along a duct to the final effluent or to a stack. Just beyond it a tube of only a few millimeters in diameter is run into the duct and there discharges the chlorine gas which is fed into it through the control apparatus from cylinders of liquid chlorine located at some convenient point.

The apparatus once installed and adjusted runs automatically, requiring little attention.

## The Physician in Industry: A Symposium

The medical and social aspects of the work of the industrial physician have received sane and enlightening treatment in Special Report No. 22 of the National Industrial Conference Board. Special movements are, during their period of development, apt to be denied the attention that they deserve from the general reader whose first interest is in some other field. To some extent this is the inevitable result of the multiplication and internal specialization of professions. The appearance of the report mentioned above is, therefore, worthy of note for its brevity and scope, which allows anyone to acquire a comprehensive and well balanced view of the present status of the movement without a great expenditure of time and study.

Members of the Conference Board of Physicians in Industry, which acts as medical advisor to the National Industrial Conference Board, have written eighteen of the nineteen sections that appear in this report. The or-

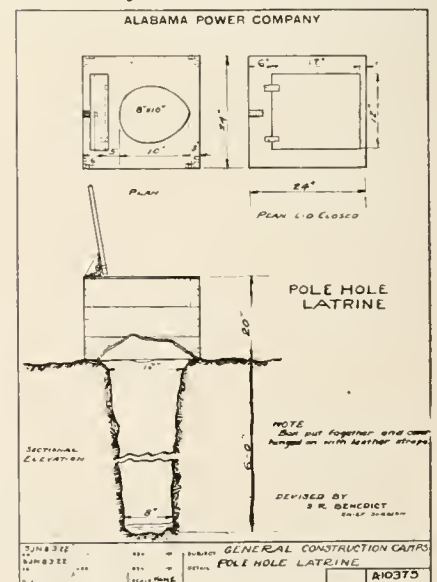

ganization of the medical department in industry, its relation to the management, its relation to the community, first-aid, records, dental work, tuberculosis and heart disease, the standardization of end results following injury, and the compensation of various injuries are representative of the subjects discussed. The concluding section is on the value of the medical department in industry from the viewpoint of the management.

The value of industrial medical departments is clearly shown. In contrast to the benefits, the common deficiencies are pointed out and the defects of present compensation laws in putting a premium on poor surgery are particularly stressed.

The common opinion among ventilating engineers that tapering in main ventilation ducts was necessary for good distribution should receive some modification in view of the recent study by Winslow and Greenburg that appeared in the *Public Health Reports* for July 28, 1922.

The contamination of cistern water used for drinking purposes by lead flashings on a roof is reported in the *Public Health Reports* for July 28, 1922.

## Sanitary Pole Hole Latrine

The question of sewage disposal in a camp is one of its most serious problems and one that must be solved before camp conditions can be considered safe and healthful. For a number of years the Alabama Power Company had difficulty in getting a latrine properly constructed. Invariably they were dug so that flies had easy access. Realizing that the men in camp were adepts in digging pole holes, S. R. Benedict, chief surgeon, devised the pole hole latrine.

The hole is dug six feet deep with a diameter of 8 inches at the bottom and 12 inches at the top, a wooden box 20 inches high is built over the hole and the lid is hinged with leather straps.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## The Game of Health in Minneapolis Schools

Teeth, Posture, Nutrition Emphasized  
in Consistent All Year Health Program

BY NILS JUELL, D.D.S., CHAIRMAN HEALTH PROMOTION COMMITTEE, MINNEAPOLIS BOARD OF EDUCATION,  
MINNEAPOLIS, MINN.

IF BRIGGS, the cartoonist, could have stepped into a certain Minneapolis grade school one morning a few months ago, he would have been a witness to a living enactment of his own slogan, "When a feller needs a friend." The picture presented in this particular instance had as its central figure eleven year old Johnnie, the only boy in the Seventh B grade of the Longfellow school who did not possess a toothbrush. For weeks in hygiene class he had reported to the teacher, "No toothbrush!" and, consequently, for weeks, the grade of the class had stood at an ignominious C. At last the stigma had become too much for the class to bear. And so the boys had assembled with Johnnie in their midst to decide what should be done about getting him a toothbrush.

Poor Johnnie that day was in the deepest gloom of any boy in the Longfellow school. He was sternly warned that if he did not have a toothbrush by the time the hygiene class next assembled, the other fellows in the class would put their money together and buy him one. Mrs. Zoa Schmedler, physical training and hygiene instructor, was met by a radiant Johnnie when the Seventh B boys next assembled for their hygiene lesson. "I've got my toothbrush!" he announced triumphantly. The grade of the class that day soared to a brilliant "A."

This true incident illustrates the vital way in which the health and hygiene program in the Minneapolis public schools has gripped the imaginations of the boys and girls. The hero

of the "gang" in a Minneapolis graded school is not the one who scorns to brush his teeth, drink milk, and sleep ten hours at night. Rather, he is the boy who has a 100 per cent record for good teeth, correct posture, and normal height and weight. The "Health Game" is one in which every child aspires to excel as earnestly as he aspires to excel in football, baseball, or track events.

The "Health Game," in its present form, introduced into the curriculum of the Minneapolis Public Schools, is the result of active cooperation between school superintendent, school board, and the men and women in the field. The Promotion of Health Committee of the Board of Education consists of the superintendent, William F. Webster, three members of the Board, and the health commissioner, who is also school health director. The committee has functioned almost three years and has met with unusual success in dealing with the obstacles common to cities of our class. It has been an interesting development. The job of health promotion which it assumes was then in its second stage of development, the first stage having been that of Medical Inspection, grandfather of all school health work, who made his first appearance in Minneapolis schools in 1909. The efforts of "Grandad Medical Inspection" were later merged into those of his son, Health Supervision, whose family now includes eight physicians, fifty-four nurses, three dentists, three dental hygienists, a dental supervisor, special hygiene instructors and a gen-

eral hygiene instructor, nine bath attendants, and the necessary corps of stenographers and clerks. Next in the line of descent, the lusty grandchild, Game of Health, protégé of the promotion of health committee, is still in his infancy in Minneapolis, but he promises to become the sturdiest and most popular member of his dynasty. With the school children he has already won popularity which his forebears never enjoyed. Time was when the term "health" to the mind of the school child connoted the figure of the medical inspector, grim, black-bearded, with a high, black silk hat and a long, black satchel out of which came all sorts of nasty medicines and frightful instruments. Health inspection day was a day of dread in every classroom.

"Health" means something quite different to the Minneapolis school child today. It is as much a part of his daily education as arithmetic, gymnastics, or basket ball practice. In fact, the game of health is so closely linked up with all of the other games he plays, that he can no longer separate it from the others. To fail in the health test is as vital as to fail in a history test.

The game of health in Minneapolis Public Schools has five distinct aspects insofar as it makes an appeal to the child's pride and competitive instincts. Those five aspects involve instruction in dental, nutritional, and posture hygiene; physical training and athletic; and special instruction for defective groups, such as the blind, crippled, deaf, tuberculous, and

With the assistance of 125 local dentists a dental survey of all Minneapolis school children was completed in thirty days. General health conditions of the pupils were also noted at this time.

subnormal. The normal child divides the game of health into the first four components. He must have a healthy, well-cared for set of teeth; he must eat and sleep properly in order to keep up the normal standard of height and weight; he must sit and stand and move correctly, in order that his body may grow straight; and he must make his mark in the gymnasium and on the athletic field. If he is a child with some physical handicap, he still carries on all those things, but he is first fitted into the special group to which he belongs in order that he may have a special chance to overcome that handicap and so measure up to normal standards.

To aid the normal child to attain the standards of health held before him, a number of specific agencies in the schools and also a number of extra educational agencies are at work in Minneapolis. In the schools there are special classes in hygiene instruction in the seventh and eighth grades; a system of physical education which starts the child's physical training as soon as he enters the fifth grade; an oral hygiene department which comprises dental clinics, and prophylactic instructional centers; and a system of "Health Habits," play which is begun in the kindergarten and carried throughout all the grades. Extra-educational agencies assisting in the health program include the Woman's Community Council, a private organization which operates ten demonstration nutrition clinics in the schools. The National Dairy Council assists the Woman's Community Council in promoting the establishment of milk stations for the under-

nourished children and also aids to establish the milk habit in the spoiled ones. The Board of Public Welfare is particularly interested in medical inspection in the schools. The Minneapolis District Dental Society last year contributed a unique and valuable dental survey of forty thousand children in the five primary grades of all the schools. The juvenile court and various private welfare agencies also assist in studying the problems which affect the school child's health and build up community safeguards which minister directly or indirectly to the physical welfare of all of the children.

Outstanding among health projects in the Minneapolis Public Schools last year was the extensive dental survey conducted by the oral hygiene committee of the Minneapolis District Dental Society, Dr. Elmer S. Best, chairman. This survey to which one hundred and twenty-five local dentists

devoted their time gratuitously, assisted by the school board's dental supervisor, Dr. Denton White, was completed in approximately thirty days. The Society has pledged itself to repeat the survey on a still larger scale in the coming year. What the survey undertook to obtain was a record of the general health of each pupil, including not merely the condition of his teeth but also the condition of his tonsils, heart, eyes, ears, and his habits of eating, sleeping, and breathing. On each child's card were recorded thirty-seven facts, general condition of his teeth and descriptive of his general health, the general condition of his teeth and mouth, and the condition in detail of his six-year molars.

Some of the questions which the survey undertook to answer in forty thousand cases were: What is the child's general health? Good, fair, or poor? Are his tonsils defective? Has he cardiac trouble? Has he any eye defects? Has he any ear defects? Does he breathe through his mouth? Has he had any of the following: Measles, scarlet-fever, mumps, diphtheria, whooping cough, chicken pox, smallpox, pneumonia, and tonsillitis? Does he eat candy or pastry between meals? What is his home beverage, coffee, tea, or milk? Is his occlusion normal? What is his masticating efficiency? Does he use a toothbrush daily? Has he decayed or infected deciduous (baby) teeth? Are any of his permanent teeth missing, decayed, or infected? What is the condition of his six-year molars?

Acting upon the facts disclosed by this survey, the Board of Education proposes to inaugurate throughout the school system next year a series of lectures on dental hygiene. These lectures will be delivered by the teach-

The awe-inspiring formality of the old school medical inspection has given way to a fascinating game of health impressed on the child mind by pageantry and parade.

ers themselves, who will first be trained for the class. The lectures will be made more vivid by the display of large models of the human jaw with all its teeth, presenting a clear picture of what their own mouth should look like. Furthermore, dentists in the various districts of the city will be asked to lecture before the parents and teachers in their prospective districts, in order to stimulate the fullest possible cooperation in carrying out this educational program in the schools. Finally, dentists will be supplied with certificates, one of which will be filled out and given to each child as soon as his mouth has been put in good condition by the child's private dentist or the school clinics, as the case may be. Also, each school room will post lists of the "hundred per cent" children, and when a child has all the necessary dental work attended to, he will receive a star after his name. This will put the educational campaign on the competitive basis, which should help to stimulate the pupils' and parents' interest.

Arousing a good health consciousness in the mind of every individual pupil is the object of the special hygiene classes which are emerging out of the experimental stage into the stage of standardization in our schools. To head these classes, Miss Nettie Strate was appointed as a special hygiene supervisor last year. It has been found most practical to have the physical training instructors act also as the hygiene instructors, as they have the opportunity to study the child's temperament and habits at play as well as at work. In one

Chart showing gain in weight in Minneapolis schools during the two month period from April to June, 1922.

particular graded school, where the hygiene program was most fully worked out last year, the seventh and eighth grade pupils were divided into sections, according to sex, and each section received one-half hour instruction in hygiene weekly. Since few precedents for such work were available, the instructor, Mrs. Zoe Schnedler, who also taught physical training, largely worked out her own ideas of instruction. Care of the teeth received special stress, and a demonstration of the proper way to brush the teeth was given before each class. A toothbrush inspection was also ordered and each child brought to the school the brush he was using at home. The inspection proved a profitable occasion

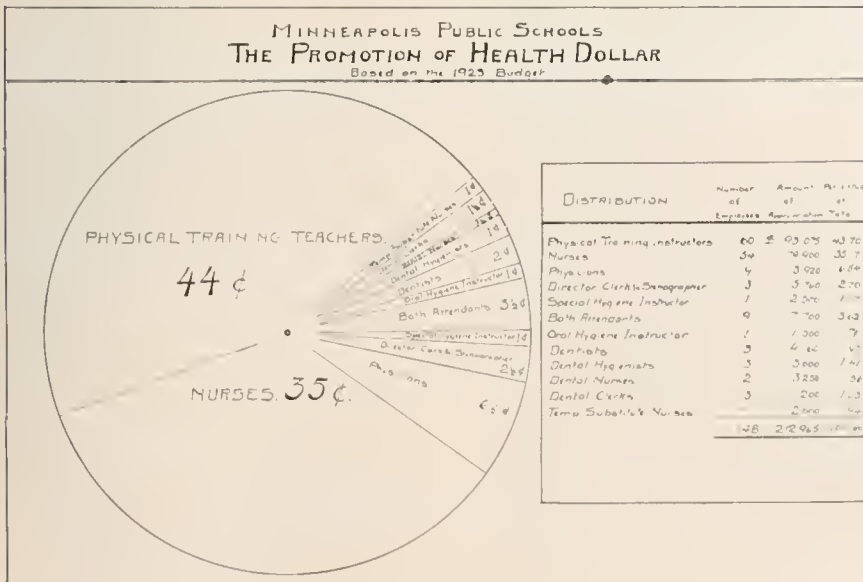

for a lecture on the condition and proper care of the toothbrush.

At the close of the inspection each child was given a card on which, for a month, he was required to record his daily toothbrushing habits. "The record for the first few days was poor, but it was almost perfect for all the classes by the end of the month," Mrs. Schnedler. "Scarcely any child's record fell below 50 per cent, and the average was about 90 per cent."

The "clean taste habit" was stressed by Mrs. Schnedler with gratifying results. It became a common incident for a child to confide, "I can't get up in the morning and eat breakfast without first brushing my teeth." The term, "garbage can" became a part of the class vernacular to designate decayed teeth; and every child, as rapidly as he could persuade his parents of the necessity, got rid of those sources of reproach.

In addition to dental hygiene, Mrs. Schnedler devoted much time to posture work. The triple posture test, administered by means of marching, standing, and general exercise, was conducted throughout the fifth to the eighth grades and the correlation between poor posture and poor scholarship, was noted in every individual case. Mrs. Schnedler's plan for the future is to conduct a posture clinic for the students having poor posture, and by means of special exercise to bring up their marks, both in posture and in scholarship.

The problem of nutrition was also attacked by the hygiene classes, as a means of supplementing the work of

The every day health work rests largely on the physical training teachers who receive 11 cents of the Promotion of Health Dollar.

the nutritional clinics operated by the Woman's Community Council. In the schools where those clinics were in operation, all the children were weighed and measured, and those found to be underweight were enrolled for clinic study. The homes were visited in order that the mothers might be taught proper feeding of their children. The school nurses and visitors cooperated in this enterprise wherever practicable.

During the past three years, five classes have been organized with an enrollment of one hundred and fifty children sent to the classes by the teachers and school nurses. The classes organized represented all types of children in Minneapolis, the Douglas School with children of the well-to-do people and living in one of the best residence districts; the Northeast Neighborhood House with children who attended the Day Nursery, all under school age; the Margaret Barry Settlement House, with children of varied nationalities, and including pupils from the Pierce School, Julia Ward Howe School, children of poorer families and living some distances from the center of the city. In all these classes practically the same percentage of underweight was found, that is, 25 per cent of the children were 10 per cent or more underweight. This proved to be rather a fatal blow to those who thought the idea was "to feed the poor."

An attempt was made to conduct the work as classes, but it was found that this required too much time from the classroom. The main idea in organizing has been to cut down time and to relieve the teachers from extra burdens. The children chosen were examined by Dr. N. O. Pearce, medical director, or someone of his staff. All children 10 per cent or more underweight were in the class whether "free to gain" or not. This was more or less a detriment to results as results, but has meant a great deal to parents in knowing that with physical defects the child cannot develop as rapidly.

In 1919 the work was carried on entirely through the mothers, nurses and doctors talking to them at stated times on the dangers of malnutrition and physical defects. Recognition of these outside agencies and thorough cooperation, as mentioned before, developed the work so that in 1921, two thousand children were weighed and measured and the weekly attendance reached four hundred and sixty-two in classes.

In the physical educational system

in the graded schools, the beginning of correlation between nutrition and physical training has been worked out. A study has been made by the physical training director of the influence of systematic physical exercise not merely upon the child's posture and powers of coordination, but upon his development in height and weight. Statistics compiled by the director show that the average fifth grade child, before he enters upon a course of systematic physical training, is below the standard in height and weight, partly because of poor posture, poor teeth, or other unremedied physical defects. Given a set of favorable factors, including the removal of physical defects and the aid of food, sleep, and the rest program promoted by the nutritional classes, the average child by the time he graduates from the eighth grade after four years of carefully planned physical training has attained the standard height and weight and, in some cases in Minneapolis, has been found to exceed the standard.

The physical training program in the grades comprises what are termed "efficiency tests" in addition to regular gymnastics and athletics. Every child is compelled to practice these efficiency tests which are often different for boys and girls and are changed every month. The following were the efficiency tests given last year: October, boys and girls, playground ball throw; November, boys and girls, basketball goal throw; January, boys, chin the bar; girls, basketball throw; February, boys and girls, Indian club race; March, boys, pushup; girls, run and catch; April, boys, hop, step, and jump; girls, basketball throw; May, boys and girls, 50-yard dash.

"By means of these simple tests, given as a compulsory part of the physical education program, the maximum number of pupils take part in athletic events, which are both pleasant and beneficial," said Mr. Tapp. "The events selected encourage all-round physical development because of their varied nature. Exercise of the large muscle group is encouraged, thus satisfying the need for a type of exercise fundamentally beneficial to the growing boy and girl."

Special health projects in Minneapolis Public Schools comprise classes in sight saving for pupils with defective eye-sight, classes for the blind, deaf, sub-normal, crippled, and for pupils with defective speech. Here again outside organizations have played their part. The Anti-Tuberculosis Society, the Society for the

Advancement of the Deaf, the Society for the Advancement of the Blind, must be mentioned. The work of the Rotary Club and the Elks' Club in behalf of crippled children has, in Minneapolis, given these organizations another good reason for existence.

A special school for crippled children, named "The Michael Dowling School," after Minnesota's late crippled statesman, was established in March, 1920. The school now has an enrollment of more than one hundred. The children are taken to and from school in busses, and receive in school not merely class work but medical treatment.

Minneapolis has two schools for its tuberculous school children. This work is in charge of Miss Kathryn Young. The Trudeau Open Air School is now in its tenth year, and has an enrollment of one hundred. It takes care of the more severe incipient cases, while the Lymanhurst School, founded in conjunction with the Lymanhurst Children's Hospital and proposed health center, enrolls the mild cases and gives them similar open air treatment and dietetic care.

The Lymanhurst School has completed its first year, and Dr. F. E. Harrington, school medical director, reports that in twelve months there were admitted to the school, one hundred and ninety-nine children, while eighty-five were discharged to be enrolled in normal classes. An out-patient dispensary was established in connection with the school last January and since that time between two hundred and three hundred children have been examined in the dispensary. The school also provides observation wards for suspected cases of open tuberculosis.

Figures gathered by the National Committee for the Prevention of Blindness in the Russell Sage Foundation Building, 130 East Twenty-second Street, show that during the first half of 1922 wood alcohol caused 130 deaths and 22 cases of blindness. It was announced that more than half of the 130 fatal cases brought to the attention of the National Committee for the Prevention of Blindness during the first six months of this year were in New York, New Jersey, and Pennsylvania. Forty-five fatalities were reported in New York, 28 in New Jersey, and 15 in Pennsylvania. Five deaths were reported in Texas and four each in Connecticut, Massachusetts, Ohio and Missouri. In the first twelve days of this year 103 of the 130 deaths were reported.

# Dispensary System of U. S. Veterans' Bureau

BY KARL SCHÄFFLE, PASSED ASSISTANT SURGEON (R) U. S. PUBLIC HEALTH SERVICE, ASSISTANT CHIEF DISTRICT MEDICAL SERVICE, U. S. VETERANS' BUREAU, WASHINGTON, D. C.

CONSPICUOUS among the features of the law\* by which the U. S. Veterans' Bureau was established was the provision for a comprehensive system of dispensaries. This measure was evolved from the experience of the three organizations which had been concerned previously with all of the functions assumed by the new bureau, the Federal Board for Vocational Education, the U. S. Public Health Service, and the Bureau of War Risk Insurance. The objects to be gained are to afford prompt service in the establishment of claims for disability incident to military duty and in furnishing medical treatment to claimants, including hospital care; the determination of their fitness for vocational training; the provision for after care or observation of convalescent and "follow-up" of post-convalescent cases; and the prevention of unnecessary hospitalization or other government expenditure.

The law provided for the establishment of one hundred and forty offices to be distributed among the fourteen districts into which the country had been divided for the administration of the War Risk Insurance Act. In each district there is a headquarter's office located in the chief city and an average of nine sub-district offices at other important centers. Thus, by providing a dispensary for each district and sub-district office throughout the United States, the process of decentralization is rendered most effective by bringing the means of satisfying the various medical, economic, and social needs of the disabled veteran, in the great majority of cases, to his very door.

In order to supply the services required, it was necessary to utilize the recent conception of "group diagnosis" combined with the accepted methods of modern social service. Thus, in addition to the superior facilities afforded, the responsibility for adjustment of claims against the Government is shared by a number of physicians rather than borne by a single individual. This involved the formation of units, comprising representatives of every medical specialty

including dentistry, together with social workers or "follow-up" nurses and the necessary administrative force with sufficient facilities to function adequately. Such organization had been anticipated by the U. S. Public Health Service, which in addition to its extensive system of hospitals and relief stations, created many local groups of specialists who cooperate under the supervision of an administrative officer or worked together in an examining office or dispensary. As a first step, therefore, all personnel, space, and equipment which had been devoted to War Risk work by the Public Health Service was transferred to the Veterans' Bureau. It was then necessary to create new units and to adopt a comprehensive scheme of organization for the whole dispensary system. The necessity for immediate standardization of method and equipment was obvious. Accordingly, a survey was made of the out-patient facilities of existing government agencies and certain leading civilian institutions, and an extensive study of the exact needs presented by the special class of beneficiary under consideration.

The needs of the veterans are those

primarily of that interesting cross section of the population which normally should be at the beginning of the most productive period of life but in which even under ordinary conditions there is the greatest incidence of active tuberculosis, venereal infections, and certain of the psychoses. There is also to be considered the personal attitude peculiar to this age, with its ambitions, freedom of expression, and impatience of restraint. Added to these elements are the effects of the stress of war, the lesions incident thereto, and the enforced illness and anxiety due to disability. The result is an aggregation of chronic and acute conditions which must be sifted out for treatment while at the same time the individuality of the patient must not be overlooked. Such a situation consisting as it does of large numbers of presumably normal, chronic, and obscure conditions presents every indication for "group diagnosis." As a consequence it was necessary to assemble representatives of all of the leading specialties, with particular provision for the two conditions which are the leading and as yet unabated causes of disability, tuberculosis, and nervous and mental disease in each of which prompt recog-

Dental Section of Detroit dispensary maintained by the U. S. Veterans' Bureau. The Detroit dispensary is one of the 140 authorized by law.

dition of early pathology and careful "follow-up" of old cases is so essential.

In the course of adaptation of the best features of modern agencies to the conditions mentioned certain general principles became manifest. The chief of these were that the physical plant must be comfortable, sanitary, dignified, and attractive, that the "lay-out" should favor a one-way traffic through the various clinics and departments with the avoidance of confusion, and that provision must be made for ease of access between related units, such as the reception room with the information desk, the social service department with the waiting-room, the x-ray with the tuberculosis, dental, and orthopedic sections, the clinical laboratory with the urologic and medical clinics, and the rest-rooms with the physiotherapy and dental departments.

The outcome of the study of the problems presented as applied to the country at large was the adoption of a classification of dispensaries according to the size or special needs of the section to be served. Thus, three types of dispensaries were decided upon, as follows:

**Type A.**—Consists of a complete unit, comprising clinics in internal medicine, general surgery, tuberculosis, neuro-psychiatry ophthalmology, diseases of the ear, nose, and throat, urology, orthopedics, physiotherapy, dentistry, x-ray, clinical laboratory, and pharmacy,

with facilities for administration and social service, occupying approximately 8,500 square feet of floor space.

**Type B.**—Consists of a similar unit in which the surgical clinic embraces urology and orthopedics, the dental clinic has two chairs instead of six, and the section of physiotherapy is omitted. The floor space occupied is 4,216 square feet.

**Type C.**—Consists simply of clinics in medicine, surgery, and eye, ear, nose and throat, with a small clinical laboratory, one dental chair and an x-ray if x-ray contracts justify its establishment, and occupies 2,352 square feet.

The following standards were adopted for the allocation of floor space:

**Class A Dispensary**

Place	Size of Room	Total Sq. Ft.
Executive office	20x20	400
Senographer's office	20x20	400
Files	10x16	160
Admission desk and records	10x16	160
Waiting room	20x32	640
General diagnosis, 6 rooms, each	10x12	720
Internal medical consultant	10x12	120
Tuberculosis consultant	10x12	120
Neuro-psychiatric consultant	10x12	120
Eye	20x12	240
Dark room	8x10	80
Ear, nose and throat	16x16	256
Surgery	20x16	320
Store room	10x12	120
Orthopedic	16x16	256
Physio-therapy:		
1. Hydro-therapy	20x16	320
2. Electro-therapy	10x16	160
3. Thermo-therapy	10x16	160
Dressing cubicles, store room and massage	10x16	160
X-Ray:		
1. Exposure room	10x16	160
2. Dark room	6x8	48
3. Machine room	6x8	48
Clinical laboratory	12x16	192
Pharmacy	12x16	192

Dental clinic (6 chairs)	12x60	720
Dental laboratory	12x12	120
General supply room	10x12	120
General store room	24x32	768
Toilet rooms (3), each	16x12	576
Women's rest room	12x16	192
Patients' emergency rest room	20x20	400

Total number of rooms.... 35 8,448

**Class B Dispensary**

Place	Size of Room	Total Sq. Ft.
Administrative office	20x16	320
Clerical office	20x16	320
Waiting room	20x20	400
General examination rooms (6), each	10x12	720
Surgical clinic	20x16	320
Eye	20x8	160
Dark room	8x10	80
Ear, nose and throat	10x16	160
Dental clinic (2 chairs and laboratory)	30x12	360
X-Ray	10x16	160
Dark room	6x8	48
Clinical laboratory	10x16	160
Pharmacy	12x16	192
Emergency rest room	16x16	256
Store room	20x16	320
Toilet rooms (2), each	10x12	240

Total number of rooms.... 22 4,216

**Class C Dispensary**

Place	Size of Room	Total Sq. Ft.
Administrative office	12x12	144
Clerical office	16x16	256
Waiting room	16x16	256
Medical clinic, general medicine chest, and neuro-psychiatry (3 rooms), each	10x12	360
Surgical clinic	16x16	256
Eye, ear, nose and throat clinic	20x8	160
Dark room	6x8	48
Dental clinic (1 chair and laboratory)	20x12	240
Clinical laboratory	10x8	80
X-Ray	10x16	160
Dark room	8x10	80
Pharmacy	12x16	192
Store room	10x12	120

Total number of rooms.... 15 2,352

The personnel to man the three types of dispensary was standardized according to the following table:

**Personnel Class A Dispensary**

- 1 Medical officer in charge.
- 1 Chief examiner.
- 6 General examiners (full time).
- 1 Tuberculosis specialist (full time or part time).
- 1 Assistant tuberculosis specialist (full time).
- 1 Neuro-psychiatric specialist (full time or part time).
- 1 Assistant neuro-psychiatric specialist (full time).
- 1 Attending specialist internal medicine (full time or part time).
- 1 Attending specialist surgery (full time or part time).
- 1 Assistant attending specialist surgery (full time).
- 1 Attending specialist orthopedics (full time or part time).
- 1 Assistant attending specialist orthopedics (full time).
- 1 Attending specialist eye (full time or part time).
- 1 Assistant attending specialist eye (full time).
- 1 Attending specialist ear, nose and throat (full time or part time).
- 1 Assistant attending ear, nose and throat specialist (full time).

1 Attending specialist physio-therapy (part time).	
3 Aides physiotherapy (full time).	
1 Attending specialist x-ray (full time or part time).	
6 Dental examiners (full time).	
1 Pharmacist.	
1 X-ray technician.	
1 Laboratory technician.	
1 Dental technician.	
3 Nurses.

The standardization of dispensary	

equipment was effected by investigation of the relative merits of the different types of apparatus designed for similar purposes and the selection of the most satisfactory. All equipment was then grouped and listed by units to correspond with the various clinics and departments. By this means it is possible to expedite requisitions either for an entire dispensary or for some particular clinic when sudden growth of service requires prompt expansion of facilities.

Dispensaries of the type of Class "A" were established in the nineteen leading cities of the United States, including the fourteen district headquarters. Seventeen dispensaries of the type of Class "B" have been opened or are about to open in the remaining cities which exceed two hundred thousand population. Class "C" dispensaries are being established in the one hundred and three remaining cities in which there are sub-district offices.

A summary of dispensary procedure as it affects the patient is as follows: At the first visit the ex-service man or woman is referred by the information clerk to the registrar who enters the name, address, age, occupation, military organization, length of service, and other essential data upon a card and refers the patient to a general examiner. The general examiner takes the medical and service history and makes a complete physical examination which includes a record of the height, weight, blood-pressure, and vital signs. He then refers the patient to the specialists whom he considers it necessary for him to see in order to complete the diagnosis. The laboratory tests required in his case are then performed and the patient is referred back to the general examiner. This physician assembles all of the reports and if necessary holds a consultation with his colleagues and makes a final diagnosis and outlines the treatment. He is responsible for hospitalization if it is indicated and for the determination of the patient's general fitness for vocational training when the time arrives.

The general examiner supplements his medical treatment by attention to the social and economic status of the patient and calls upon the "follow-up" nurse or social workers or the representative of the proper veterans' or other welfare organization for cooperation when such service is required.

The entire procedure may take a short time or may extend over a con-

siderable period depending upon the nature of the case. The use of routing-cards, messengers, and announciators has proved of great value in conveying the patient, safe-guarding his records, and reducing the time consumed.

**American Hospital Association at Atlantic City**

Hospitals should be centers of social service, especially in the way of hygiene instruction in prevention, was the statement of Dr. George D. O'Hanlon, president of the American Hospital Association, in his opening address at the twenty-fourth annual convention at Atlantic City, N. J., September 25-29.

Hospital officials should have a large and inviting field of labor in prevention, Dr. O'Hanlon believes. "The hospital superintendent who does not see opportunities for work beyond the restricted horizon of his hospital enclosure is shortsighted and misses his opportunities for the best work."

The outpatient department offers a rich field for exploitation, Dr. O'Hanlon further stated. In the development of this branch, follow up care will not only be exercised but the hospital will be relieved of the strain of providing beds for ambulatory cases.

The phenomenal growth of hospital service was pointed out by Dr. O'Hanlon. Fifty years ago only 140 hospitals including institutions for the insane were in operation in the United States while today there are 7,000, an increase of 5,000 per cent. The first ambulance service in the world connected with a general hospital was established in New York City in 1869 while the oldest training school is not yet fifty years old. Further progress is shown in the fact that while the first school connected with a hospital for the practical training of midwives was opened in 1911, today twenty-eight states have laws regulating their practice. Social service, which has come to have a recognized place in the hospital, dates back only seventeen years.

In 1883, Detroit, with its 127,000 inhabitants, spent \$7,054 on public health, or about 5½ cents per capita. In 1921, with 942,000 people, Detroit spent \$1,527,355 for the maintenance of the Health Department, or \$1.62 per capita. Of this sum, 73 cents was devoted to the maintenance of the Herman Kiefer Hospital. The maintenance item is 89 cents per capita.

# Institution Records of Value to Inspectors\*

## Detailed Reports Aid Inspection and Make for Hospital Standardization

BY RANSOM A. GREENE, ASSISTANT TO THE COMMISSIONER, DEPARTMENT OF MENTAL DISEASES, BOSTON, MASS.

**I**N discussing hospital records of value to inspectors, any one of the hospital records is of such importance that a detailed study is required as well as advice in some cases from the standpoint of an efficiency expert to assure the content of records giving the desired information sufficiently complete and accurate to satisfy critical inspection.

Since the subject is so involved it may be well to outline briefly the methods adopted by the Massachusetts Department of Mental Diseases, the aims and purposes of which are twofold.

Records in Massachusetts to be of value must be of such character that the purpose of the hospital are served, the hospital having to deal with the individual, with the individual's most interested relatives or friends, and sometimes with a most critical public. On the other hand, there are in our group fifteen state hospitals and about twenty-five private hospitals over the latter of which we exercise certain legal and supervisory powers. In state hospitals alone caring for approximately twenty thousand persons are involved legal and financial considerations to be presented to legislative bodies, the administrative council, and to the Governor.

It is therefore the purpose of the department in its supervision to maintain an inspection of state hospitals in particular which in a general way includes the following principles. (1) Standardization as to personnel, grades, pay, and quota; standardization of food as to its quality, amount, and balance; uniformity of case records; standard requirements in nurses' training schools. It seems best that hospitals should have approximately a capacity of two thousand beds. (2) Each hospital should maintain an outpatient department or clinic. (3) Each hospital should have a board of trustees and, where available, a visiting or consulting staff as well as resident staff. (4) The hospital administration should be directly under the leadership of a medi-

cal man trained in psychiatry. (5) The ratio of medical officers should be 1 to 135. (6) Staff conferences should be conducted daily if possible for the purposes of diagnosis, outlining treatment, settling questions of parole, visit, or discharge, and for making social service recommendations and recommendations to courts on observation commitments. (7) Each hospital should have a receiving ward or observation department. (8) The group of hospitals should be so classified that some may be selected for individual purposes and research, including one or more strictly psychopathic hospitals where intensive studies and utilitarian observations can be made for large centers of population. (9) Laboratories for bacteriological, chemical, and biological tests of general medical diseases as well as mental diseases should be maintained. (10) Hospital equipment should include hydro-electric occupational paraphernalia as well as general and special surgical and dental facilities. (11) They should have an adequate nursing force of standardized quota and grade in the ratio of at least 1 to 10 patients and some female nurses on male reception wards. (12) A social service department of 1 to 3 workers at least. (13) Recreation and diversion together with library facilities should be uniformly provided.

### Duties of Inspector

From the standpoint of inspection of records, it is the policy that at regular intervals the institutions be visited. The nature of institutions are such that a medical man is required for these inspections. His duties should be the visitation of hospitals to observe the general morale, to attend and observe conduct of staff conferences, to rate in a general way quality of work done by various members of the staff, character or work on wards and apparent condition of patients. He should go over records of commitment since last visit and determine if admissions to the hospital are on proper legal basis. Incidentally, Massachusetts probably has more forms of admission and commitment to state hospitals than

most other states, about twelve in all. He should examine in a general way into the various therapeutic functions of the hospital from a medical standpoint, the medical, occupational, surgical, and dental work, as well as accomplishments in the laboratory and researches of the pathologist.

From a physical standpoint, he should examine the property as to general repair, housekeeping, progress of new construction, fire apparatus, heating, water and sewage systems, bathing facilities, culinary and dining-room conditions, laundry, and appropriate and proper clothing of inmates.

Regarding records and reports, there is a system of annual, semi-annual, monthly, weekly, and daily returns to inspect.

With the farm, there are the records of milk production, reports of tubercular tests or cholera immunizations, reports of farm production and disposal of them, including work done on grounds and in stables.

In the steward's department there should be available a store room account, incoming and dispersal, so that at all times an inventory of any specific article could be readily shown on his books. He should also have a budget analysis showing his expenditures, according to ration or other allowance by the month and a similar record for expenditures on repairs, renewals, and special appropriations.

There should be weekly dietaries for various groups fed, including officers, employees, and patients. Records should be kept indicating by weight the amount of waste from kitchens and dining-rooms that comparisons might be made with ration allowance fed to pork and poultry products of farm. Coal consumption should be recorded that comparisons may be made with power, heat, and light reports.

In the treasurer's office there should be records of cash schedules, including paid and unpaid bills, advancements from state treasurer, analysis on monthly basis to compare with budget allowance and payroll, personal service quota, classification quota and time books, records of bills

\*Read before the Forty-Ninth Annual Meeting of the National Conference of Social Work, Providence, R. I., June 22 to 29, 1922.

for private support and partial reimbursements for patients' care, valuables, and patients' cash records. Inspection of above records require and have the service of an accountant from the state auditing department.

Inspection of clerks' records would include patients' individual record, which records are uniform in all hospitals and include a prescribed form of front sheet, giving the more important statistical data as to name, age, birthplace, parentage, discharge, residence, and occupation, and contain all data used on statistical cards for making report based on the statistical manual of the National Committee on Mental Hygiene. The body of record should include, first, an abstract of case followed by family history, personal history, physical examination, mental examination, psychological examination, treatment and laboratory charts, first day, third day, seventh day, tenth day, quarterly, semi-annual and annual notes, and social service record if patient has been under the consideration of that department.

In the clerks' department there would also be the ward day and night reports and census, daily and weekly, daily temperature records from wards, fire drills, restraints, seclusions, accidents of sudden deaths, narcotic, drug and alcohol records, pharmacy, library, and entertainment records. The foregoing records would be those in which the medical inspector or investigator would be concerned.

From the various institutions there would come to the office of the department a duplication of such records for their use for compilation of statistics and purposes of supervisory administration and laying down of broad general policies. In the office of the department, other than the medical inspector, there was in 1918 established a farm investigator who deals specifically with the agricultural interests of the institution and bases recommendations for standardization on such inspections and farm records.

The social service has for some time had a department head who deals specifically with social service problems for the purpose of correlating and coordinating the work.

In the business agent's office there has this year been added an engineer who deals with engineering problems and new construction. The business agent's department has for some time by means of holding monthly meetings of the various stewards directed the

work of combination buying and the making of term contracts for food and other supplies, including coal and new construction contracts. All institutions participate equally in the advantages of such purchase as well as standardization of quality of supplies.

The assistant commissioner reviews daily the reports of commitments. On the basis of these and with weekly and monthly census returns he establishes equalization of population by notification to the courts and transfer of patients. He also, through a system of investigation from the support department whose agents visit all new admissions, determines the persons subject to deportation and arranges for the same. The support de-

partment also conducts its investigation as to the finances of the patient and arranges maintenance or partial reimbursement for patients.

Insofar as the department has developed, the records are commensurate with the needs and answer the purposes of outgoing inquiry and incoming information. Further developments and new divisions are in contemplation and will require much study previous to establishment. The most recent and difficult problem is that of the division for feeble-minded where the department has already in progress a state-wide census including clinics for all children of the public schools that are three or more years retarded in school work.

## Housing for Employed Women

ANYONE who stops to consider that of twelve million working women in the United States a large proportion do not live at home will realize that housing for working women is indeed a problem. Even where there are available rooms landladies proverbially desire men roomers. Many organizations have sought to alleviate this situation and foremost among them has been the Y. W. C. A. which for years has attempted to furnish suitable dormitory accommodations for girls.

The dormitory in the activities building grew out of the need for living quarters for girls who were strange to the city or who had no suitable rooming place. From an economic as well as from a health viewpoint, this plan has not proved wholly successful. Blanche Geary of the Architectural and Economic Bureau of the National Board, Y. W. C. A., points out. In the first place, the activities building is usually located in the heart of the business district where noise, heat, and lack of fresh air make living conditions uncomfortable. Such buildings necessarily occupy high priced lots and are of expensive construction, and the devoting of several stories of such a structure to living quarters entails needless cost.

The present plan which the Y. W. C. A. considers the most feasible is the construction of special dormitory buildings in resident districts on quiet, well paved streets. Such buildings to be operated on a 4 to 6 per cent return on the entire investment in land, construction, and

equipment. For a metropolitan city in which a fireproof building must be erected on the least possible land, 60x100 feet is sufficient providing elevators are installed and a high building is desirable. For a lower building of basement, ground floor, and two stories 180x125 feet is required.

In such a building bedrooms should be single and should have a plastered closet and a complete set of furniture including an iron bed with hair mattress and good pillow, a bureau or chest of drawers with mirror, a table for sewing, books, and writing, three or four shelves over the table, two chairs, one straight and one low easy chair not a rocker, and a rug.

Plumbing should be grouped in convenient locations in the proportion of five beds to one bath, six beds to one toilet, and five beds to one wash-basin. Each wash-basin should be enclosed in a partition with door to insure privacy. There should be one sink on each floor for the use of scrubwomen.

The building should also contain a laundry for the residents' use with possibly twenty-four washtubs, with steam dryers, and six to eight ironing boards; a trunk room to accommodate one trunk to each bed; an infirmary for doubtful or contagious cases pending removal or other temporary service. If space permits, the building should be equipped with a kitchenette with sink, gas ring, and small china closet, and with a sewing room with large cutting table, iron, mirror, and sewing machine. The dining room should be large enough to seat the full number of residents.

# Health Activities in a Recreational Program

By THADDEUS SLESZYNSKI, DIRECTOR, HOLSTEIN PARK RECREATION CENTER, CHICAGO, ILLINOIS.

THE new child health program with its emphasis on weighing and measuring, on playing the health game, on nutrition classes, on more thorough physical examinations, and on a better adjustment of the child's daily program to his physical needs—has it a place in the playgrounds and recreation centers as well as in the schools? If not, the recreation centers and playgrounds should cooperate with the schools and health agencies at least to the extent of not undoing the work that these agencies are trying to accomplish. If so, recreation workers need to determine what adjustments in the recreational program are necessary to make a constructive contribution toward raising the health standards of the next generation. In either case, both recreation and health workers should consider what are the relationships of this new health program to the recreational activities as they have been developed in our centers and playgrounds.

With the rapid growth of the playground movement and in the effort to serve as large numbers as possible, the recognition of different individual needs has been overlooked. Physical educators have always insisted on a physical examination as a prerequisite to meeting the individual needs of their students, a principle which has been followed in practically all our institutions of higher education. Many public schools throughout the

country have also come to regard this as a necessary part of physical training and athletics. The development of medical inspection in the schools has emphasized the need of adjusting the child's daily program to his physical capacity. However, in our recreation centers and playgrounds with their fully equipped gymnasiums in charge of trained instructors, children and young people are often enrolled without even a superficial physical examination or the simplest heart test. The scales generally found in the boys' gymnasium are used chiefly to determine the eligibility of boys and young men to participate in athletic events in which classification is made according to weight. Many instructors indiscriminately permit these participants to reduce in weight in order to become eligible to play on teams on which they are needed.

Athletic tests are given in which every "healthy boy and girl" is encouraged to participate, but no effort is made to determine who are healthy. Several of the tests for girls as well as for the boys are purely endurance tests in which the children tend to exert themselves to the limit of their strength. It has been estimated that in some communities the physical standard of the young people has been raised as much as thirty per cent through these tests, but it is quite as possible that the health standard of the group might

have been lowered at the same time, or at least remained unimproved. Clearly, it becomes the task of the recreation worker to find out the facts.

Recreation workers do not usually make use of the health service of the public school. Though the school physicians and nurses are attempting to improve the physical condition of many of the children who attend the recreation centers and playgrounds after school hours, the recreation workers take no account of this. An incident which took place in a school in the neighborhood of Holstein Park well illustrates the need for closer cooperation between the two agencies. The principal of the school told a boy suffering from hernia that the doctor had forbidden him to take part in any of the physical training and athletic activities, but met with the reply, "I don't care, I can go to Holstein Park and get all the athletics I want."

A similar lack of coordination is evident between the work of the health agencies and the recreation centers. A boy who participates in all the activities of the center and who is there most of the time, early and late, but who appeared to be in poor physical condition was found on questioning to have attended the nutrition class at the Municipal Tuberculosis Dispensary for more than a year. He had discontinued attendance because he did not want to re-

Holstein Park Recreation Center is a typical recreation plant. Millions of dollars have been spent throughout the country on community houses of this character. Few of them are being used to full capacity. The question is raised whether they could not be utilized more intensively for raising the health standards of their communities.

"Chinning," an athletic test for boys, really an endurance test. This boy is one of the most active boys at the playground. The nutrition worker at the Municipal Tuberculosis Dispensary had urged him to rest but at the center he had been permitted to be active all the time.

main at the summer camp of the Municipal Tuberculosis Sanitarium, where he was sent the previous summer. The records at the Dispensary show that he has tuberculous glands, and that he has not been a cooperative patient. His physical condition demands that some adjustment be made in his daily program, but the recreation center had unwittingly been undoing what the Municipal Tuberculosis Dispensary was trying to accomplish.

#### Progress in Coordination

Some progress has already been made in coordinating health activities with recreation programs. The Public Athletic League-Children's Playground Association, of Baltimore, employs a public health nurse as supervisor of its health department. For the past few summers health activities have been conducted in all the playgrounds under the jurisdiction of this organization. With the cooperation of the Maryland Tuberculosis Association, the Modern Health Crusade has been introduced. Every summer all the playgrounds make competitive effort for the highest standing in this activity. The children are weighed and measured in most of the playgrounds. Health poster contests are held and health plays are given. Spe-

cial talks on health subjects are arranged and demonstrations in home nursing for "little mothers" are given. The playgrounds of Newton, Mass., have a supervisor of health work, and health instruction has been given through the medium of play. Children were enrolled in the Game of Health and many common games have been adapted for use in putting across the health message.

In Cleveland, half pint bottles of milk are sold at cost in all the playgrounds under the direction of the Cleveland Summer Milk Booth Association, in order that children who have formed the habit of drinking milk in the schools should have every opportunity to obtain it in the summer, instead of reverting to pop and all day suckers.

At the Lake Shore Playground in Chicago a director, who was a medical student, introduced physical examinations for all boys and girls attending the gymnasium classes. The service was appreciated by the young people, and some very helpful advice was given on the basis of the findings made. The work has received less attention since the director resigned and another non-medical director appointed. There are no doubt many other communities in which some health work has been attempted in the recreation centers and playgrounds.

#### Holstein Park Experiment

At Holstein Park Playground and Recreation Center an intensive experiment has been conducted during the past school vacation with the cooperation of the Elizabeth McCormick Memorial Fund, the Chicago Tuberculosis Institute, the Michael Reese Tonsil and Adenoid Clinic, the Municipal Tuberculosis Dispensary and a neighborhood physician, Dr. S. Musial.

Literature explaining the Modern Health Crusade was distributed to more than two hundred children attending the playground. Those who enrolled were weighed and measured. The records of one hundred eighty-nine boys and girls include forty-five, or 25 per cent who are 10 per cent or more under weight for their height, according to the schedule of Dr. Wm. R. P. Emerson. Meetings of the Modern Health Crusaders, with an average attendance of forty have been held every Wednesday, at which the children report their progress. At these meetings activities have been scheduled similar to those arranged in the playgrounds of Baltimore. Naturally the results have not

been as satisfactory as in Baltimore because there is lacking the spirit of competition with other playgrounds.

A physical examination was offered to those boys and girls who were most underweight or who on inspection by the nurse appeared to be in greatest need of medical advice. To September 1, thirty-seven children were examined either by Dr. Musial or at the Municipal Tuberculosis Dispensary. In every case one or more physical defects were found, and the questioning of parents and children disclosed bad health and food habits on the part of those affected. Twenty-one children were referred to a throat specialist for examination. Eighteen of them followed this advice and of these, sixteen were advised to have their tonsils removed. Thirteen have already had the tonsilectomy performed and one other has made arrangements for this. In only five of these sixteen cases had the patients realized the diseased condition of their tonsils. In thirty-four cases dental treatment was advised and secured.

Twenty of the thirty-seven children who were given physical examinations have been under close supervision through attendance at a Nutrition Class which meets every Monday. The progress of this group during the ten vacation weeks has not been satisfactory as compared with that made

"Balancing Beam," a test for girls which is not an endurance test merely, like "Traveling the Rings."

by other classes. However, there are certain facts that must be considered. Ten of the fourteen who had diseased tonsils had a tonsilectomy performed before the end of the vacation period. Practically all of the children attend the playground regularly and have found it difficult to refrain from strenuous play and to take the rest periods as prescribed. Furthermore, five of the girls entered the athletic badge tests, three of them having had their tonsils removed about the same time. Two of these girls made the highest record required for older girls on the traveling rings—one hundred in one continuous trip. Not one of the five made more than the average gain in weight for the ten weeks, and two made no gain at all. Though there may be differences of opinion concerning the relation of weight to undernourishment, most physicians would not approve of endurance tests for children under medical supervision for undernourishment or the correction of physical defects. The children who voluntarily submitted to physical examinations were not discriminated against in these tests because that might make the examinations unpopular during this initial period.

Of the forty-four girls entering the

athletic badge tests who were weighed and measured, only fifteen were found to be up to weight for height. Out of twenty-seven girls who won either a gold, silver, or bronze pin, only eleven were up to weight for height. Only one of the seven girls who won gold pins was up to weight. Had physical examinations of the whole number been made, there would no doubt have been disclosed other cases of undernourishment and physical defects.

The facts gleaned from the brief experience indicate that there is a danger of recreation centers and playgrounds running counter to what the schools and health agencies are trying to accomplish, by permitting all children to take part in any and all athletic activities without any attempt being made to classify them according to their physical capacity, leaving the choice of activities entirely to the inclination of the individual child. Herein lies an opportunity for greater service which the recreation workers should not be slow to grasp. As the responsibility of the school for the physical welfare of the children has increased, so must the playgrounds aim to do more than keep the children off the street and give them a good time.

#### Plan for the Future

This experience during the summer months has suggested a health program which will fit in with the indoor activities of the recreation centers of Chicago. Mr. V. K. Brown, Superintendent of Playgrounds of the South Park Commissioners, has pointed out the necessity of putting a new activity like a Good Health Club on a competitive basis so that the rating of a club and its members might be measured in the same manner as are measured achievements in the already existing activities. Keeping this point in mind, we have outlined a plan for marking the standing and progress of the health clubs and their individual members so that they might be compared with one another. A rating will be given on each of the following points: (1) Report of physical examination, the report to be on a standard blank provided by the recreation center. (2) The physical condition as revealed in the report. (3) Weight as compared with height, (this item might be omitted if there is a disagreement as to the importance of this relationship.) (4) Some gain in weight. (All normal growing children should make some gain in weight). (5) Cleanliness and general physical appearance.

This girl cannot participate in athletics on account of cardiac trouble. Her picture shows her progress chart in the nutrition class. Why not make her efforts and progress toward becoming a healthier girl count as much as winning of athletic games by others?

"Traveling Rings," an athletic test for boys and girls. Nine girls who were under medical supervision attempted to travel one hundred rings in order to make the maximum of one hundred points to be counted toward the winning of an athletic badge. This exertion to attain a high physical rating inevitably interfered with success in raising their health standard.

(6) Good teeth or the repair of carious teeth. (7) Correction of physical defects, (tonsils, adenoids, spinal curvature). (8) Regular attendance at meetings of the club. (9) Junior sanitary police duty to the center or some service to the club. In this way the members of the health clubs can contribute their share of points, the total of which will determine the competitive standing of their center. Boys and girls can thus help their playground get a higher standing by becoming healthier themselves and by interesting others to do likewise.

During the coming indoor season, a health club on these lines will be organized at Holstein Park, but with the disadvantage of not being on a competitive basis, because, for the present, health clubs will not be started at the other recreation centers. The children in the gymnasium classes will be weighed and measured, and physical examinations will be arranged for those who desire them. By checking up the enrollment with the reports of school physicians and nurses of the neighboring school it is expected that much useful information will be obtained. A special fund may be secured by one of the health agencies for the employment of a nurse on part time who could attend to all the necessary follow up

The nutrition class at Holstein Park Recreation Center. It is proposed to give credit for improvement in health as well as for success in athletics.

work, and of a special instructor fully qualified to conduct a class in corrective gymnastics and who could also, advise the instructors concerning adjustments that can be made in the program of boys and girls who would be benefitted by this special attention. There will also be opportunities for such an instructor to give helpful suggestions concerning the regular program of work.

Certain objections have been raised to making health activities a part of the work of recreation centers and playgrounds. (1) The objection that the chief purpose of the center is to serve the recreational needs of those who are healthy and physically fit ignores the fact that about one-third of our young people are physically deficient and that this group is entitled to service. Furthermore, the situation seems to demand a physical rating. (2) It is held that recreation centers should not be given a sanitarium atmosphere by permitting children to take their prescribed rest lying in a well ventilated and otherwise unused room. Neither should the centers be commercialized by permitting the distribution (or sale at cost price) of milk to children in need of this additional nourishment between meals. Both of these practices have, however, been introduced into many schools throughout the country without turning them into sanitariums or milk stores, and without lowering the standard of service to normal children. (3) It has also been held that the equipment needed to conduct health activities takes up space which is needed in the centers for purely recreational purposes. This may sometimes be the case, but the necessary adjustments should be worked out so that the service of both agen-

cies to the community need not suffer. This can be done only through the closest cooperation. (4) Another objection is that intensive service to a small group can be given only at

## Child Health Demonstrations

CITIES in the upper Mississippi valley region which come within the population limits of from 15,000 to 25,000 are eligible for consideration as the site of the first of three child health demonstrations which the special Child Health Committee, which is to administer the Commonwealth Fund appropriation for preventive health work for children in the United States, proposes to locate in different parts of the country. The general purpose of these demonstrations is to assist these cities in safeguarding the health of mothers and promoting the sound, normal development of babies, boys, and girls, with the greatest freedom from disease, in order that these three communities may develop comprehensive plans for the health of their children that may be an inspiration and help to the rest of the country.

The area from which the first city will be chosen includes the states of Illinois, Indiana, Iowa, Kansas, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, and Wisconsin. Important qualifications, besides those of population and location, are that the infant mortality rate shall be approximately 100 per 1,000 live births or greater, and that the community shall show a desire to cooperate in the work and offer a reasonable assurance that those parts of the program which prove to be sound shall be continued by local support.

the expense of neglecting the large majority. However, it is only through devoting part of our energies to small groups that the new needs of the community as a whole can be discovered and service adjusted accordingly.

The splendid system of all-year-around playgrounds and recreation centers which exists in Chicago offers an unusual opportunity to develop health activities on a competitive basis in all the centers. Whether the playground authorities or a local health agency should initiate this constructive piece of work is yet to be determined. However, it is certain that every community which has one or more summer playgrounds can use them for the health as well as for the recreation of its children. The consistent program demonstrated during the past summer vacation at Holstein Park Playground can be worked out in any playground however small.

The organizations which the Commonwealth Fund has asked to join in directing these important demonstrations are the American Child Hygiene Association, the Child Health Organization of America, the National Health Council, and the National Child Health Council.

The work in the community will be in immediate charge of a resident director who will report both to the Committee in charge of the demonstrations and to the representatives of the community. This director is to be assisted by such paid staff of nurses, an educational director, and other necessary assistants as may be necessary, all of whom will as rapidly as possible, if not at once, assume the status of local workers. Careful records are to be kept so as to make it possible to measure the results of the work and compare them with those in other communities where especially active work is being done. The cooperation of private physicians is recognized as of great importance, and the work will be planned to supplement and stimulate their practice rather than to trespass upon it.

The Committee believes that a period of five years should be allowed for the results to prove fairly conclusive. The Child Health Committee maintains headquarters at 532 Seventeenth St., N. W., Washington, D. C. Courtenay Dinwiddie is its executive secretary.

# Teaching Health in New York City Schools

## Chew Chew and Dog Creamo Painlessly Instill Health Knowledge and Habits

BY BERTRAND BROWN, NEW YORK CITY.

THAT pedagogy has its disciplinary functions few persons born in Pilgrim-pioneered America will deny. But as to the places in the schools' curricula where children should be trained to endure a certain amount of mental chastisement "to harden the will," opinions widely differ. There seemed, however, to be unanimity of view recently among some sixty-two principals of as many public schools in New York City that the teaching of certain fundamentals of personal health and hygiene to children in the grades might well go on without any disciplinary by-product.

The circumstance was this. The New York Tuberculosis Association sent questionnaires to the above mentioned school executives asking them to state which method they preferred to have employed by the organization in bringing its health propaganda into the schools, that of a lecturer or that of a clown. Unanimously they spoke for the clown. But two voices called for the lecturer and these asked also for the clown.

The Association has experimented for several years to find some effective means of painlessly instilling certain vital impressions on young minds which, applied and adhered to, would result in more vigorous bodies. The clown's triumph has proved to be the Association's triumph and also the triumph of the health lessons. "Chew-Chew" accomplished more in forty minutes than one can in weeks of class room instruction, was the way one principal summed up the experiment.

"Chew-Chew" is the entertaining educator's clown name. In private life, he is A. J. Schneeman of St. Paul. A knowledge of the basic principles of health and hygiene, a keen understanding of child psychology, skill in magic and drollery, and a wealth of personal magnetism are the tools he carries in his kit of teaching technic.

For boys and girls of grade school age, "Chew-Chew" advocates ten hours of sleep. Or rather, "Chew-Chew" does not advocate the matter at all. Creamo, a small white dog with black ears and shoe button eyes

tells the children with his worsted paws that he goes to bed at nine and sleeps until seven with windows wide open. From his audience, "Chew-Chew" calls to his aid two small boys, one robust and healthy, the other pale and wan. "What do you drink for breakfast?" he asks the hale lad. "Milk" is the ready reply. Creamo nods his bushy head in approval and his master smiles.

"And what do you drink for breakfast?" Fidgeting under the rising inflection of the "you," the frail boy ashens and answers "coffee." "Chew-Chew" and Creamo drop their countenances in pity.

Then, to the astonishment of the audience assembled and with the as-

invariably obtained to the glee of Creamo, and always there follows a unanimous pledge to drink more milk. Trick after trick follows with apples, oranges, potatoes, and eggs, the purpose of which is to impress these foodstuffs lovingly on the memory of the youthful audience.

Blotters shaped like a milk bottle and containing a picture of "Chew-Chew" and Creamo have been published. These souvenirs bear this message from the clown to boys and girls:

Dear Boys and Girls:

I want you to have my "milk picture" to remind you of the simple rules to follow for good health:

Fresh air.....All the time.

Wholesome food..Especially fresh fruit and vegetables—eat slowly.

Sleep .....Plenty of it—windows open.

Teeth .....Brush them twice a day.

Baths .....At least two a week.

Water .....Several glasses a day.

Remember what "Creamo" taught you about drinking three glasses of milk a day.

I hope you are getting on well with your studies.

It always pleases me to get letters from my little friends.

Yours for Good Health,

CHEW - CHEW.

"For the benefit of the grown-up element," writes the *New York Evening Sun*, "let it be known that Chew-Chew" is the only power that will move modern childhood willingly toward the bathtub. He is moral persuasion personified."

There is nothing patronizing in the attitude of A. J. Schneeman to his youthful audiences. There isn't an "ought to" or "must" in his entire vocabulary. Keenly conscious of the importance of his crusade to build up the health of children and create resistance to germs at the age when a child is most susceptible to them, in "Chew-Chew's" vocabulary there is no mention of the dreaded white plague. Instead, there is much encouragement in the drinking of milk and the eating of fruit and vegetables. And every time "Chew-Chew" craftily gathers up his effects and says: "Well, I guess it's time to be going," a vociferous "No!" from his audience proves how painless is his pedagogy.

That the clown, with his flaming thatch of hair, his funny face, and his astonishing tricks makes a vivid impression on his youthful spectators, is evidenced by their letters—which

The smile, the dog, and the make-up which aid in transforming A. J. Schneeman of St. Paul into "Chew-Chew" the health advocate of the New York Tuberculosis Association.

sistance of the stronger boy on stage, "Chew-Chew" pumps a quantity of coffee from the elbow of the weaker lad. The latter is given a glass of milk, and as he drinks it—lo! and behold!—the muscles in his arm swell conspicuously, showing that "milk makes muscle."

The result expected to follow such a first hand demonstration is a unanimous vote on the part of the youthful audience thenceforth to abstain from coffee drinking. This result is

Whether he takes eggs from healthy boys' elbows or turns coffee into milk under the alert gaze of wondering eyes, "Chew-Chew" has no trouble in holding the attention of his audiences.

are the most valued part of his morning mail.

In the following poem one grade school pupil attests to the effectiveness of "Chew-Chew's" teaching:

Chew-Chew says to go to bed  
At nine o'clock at night

So that in the morning  
We will be fresh and bright.

A glass of milk for every meal  
Will make us strong and gay,  
A soft boiled egg, a little fruit  
And lots of outdoor play.

At morning for our breakfasts  
Our food we well should chew  
And not drink tea or coffee—  
Oh, that would never do!

And having given this advice  
Our health clown turns away  
To give his thirsty pup some milk,  
But he'll come back some day.

The New York Tuberculosis Association concentrates much of its educational work among the children of the metropolis. Every popular and modern method is utilized—attractively printed colored literature, "movie" films, the out-of-the-way reaching Healthmobile, illustrated lectures, miniature exhibits, nutrition classes, and visitations of open-air schools. No plan of pedagogy, however, has proved more effective than "Chew-Chew's" health performances. And who will say that it is not because his lessons are sugar-coated with event after event of long remembered jollity? It is reported that "Chew-Chew's" precepts are to be taught universally through motion pictures. This should be welcome news to parents and teachers who have not learned his art of painless health pedagogy and will delight juvenile movie fans.

## New York State School Health Service

### Knowledge of Personal Hygiene Is Right of Every School Child

BY FLORENCE A. SHERMAN, M.D., STATE DEPARTMENT OF EDUCATION, STATE ASSISTANT MEDICAL INSPECTOR SCHOOLS, ALBANY, N. Y.

IN connection with the school health program in New York State three points might well be emphasized: (1) A brief history of the state work; (2) results achieved in the past six years since the work has been actively functioning; (3) the scope of future work. In passing I cannot refrain from mentioning Dr. S. Josephine Baker who established one of the first good systems of medical school inspection. Dr. Baker's vision and ability in formulating a scheme of health work has made the New York City system one which has been followed by many municipalities. Health work in the schools of the State was made mandatory in 1913 but not until 1915 did a director assume office. For two

years he worked alone. In 1917 a state supervising nurse was appointed, but not until 1918 was a substantially additional force appointed so that today our department consists of a director, two assistants (man and woman), supervising nurse, two mental deficiency experts, direct special classes, nutrition expert, director oral hygiene, instructor of hygiene, and three stenographers.

The State of New York is an enormous field to cover and so far only the surface has been scratched. Our territory includes all the state except New York City, Rochester, and Buffalo. Seven hundred thousand children, 3,500 teachers, 1,400 medical inspectors, 250 school nurses come directly under our supervision. It will be seen at a glance that our duties are to a large extent supervisory—only

occasionally can we do the intensive group work because of still insufficient force for the territory to be covered. Surveys have been made and there has been an endeavor to use the State staff when most needed. We are lecturing in normal schools, at teachers conferences, parent teachers associations, granges, and other organizations in order to stimulate interest and make people better acquainted with what our health program stands for.

A large amount of work has been done and results obtained in spite of many handicaps.

The figures cited cover the period from 1915 to 1921. Children registered in the cities and villages numbered 1,920,230; 1,343,289 examinations were given; defects found were 102,657; number of defects 401,689.

\*Read at the annual meeting of the New York State Women Medical Association, Albany, N. Y., April 17, 1922.

Children registered in the rural schools were 1,494,104; examinations 1,195,420; defects found 107,505; defects corrected 256,302. The per cent of pupils examined in the rural schools was greater in proportion to the registration than in the cities and villages—69 in the cities and 80 in the rural districts, but the per cent of correction was much lower, 30 in cities and 23 in rural. This was due to the difficulties of obtaining dental and medical advice, we believe, rather than to the indifference of parents and lack of interest on the part of the school doctor, nurse, and family physician.

The actual corrective measures attained, although very important is not the most important part of this work. The fact that attention has been focussed upon the health of the child in the home and in the school is still more important and far reaching, our whole school health program today being educational. It is impossible to legislate measures to compel parents to care for their children in these matters.

While education is the greatest safeguard, much good work has been done along corrective lines as well as bringing about the health viewpoint in the home and school, that of keeping children well, having them enter school physically fit, establishing them in normal health habits of sleep, bathing, food, mouth hygiene, water drinking, toilet habits, rest, play, posture, and breathing without which no boy or girl can maintain health control. This is the work of the parent, the doctor, and the teacher of today. The coming doctor will be employed to keep people well, not to cure them after they become sick. Periodic physical examinations for children and adults is fast coming to be recognized as an economic measure in the home and in the community. This is as it should be. The strange thing is that this common sense viewpoint has not prevailed long since.

The scope of future work is to emphasize preventive measures as well as to aid materially in making corrective measures possible to more children. We are establishing hospital units throughout the state in the various counties whereby rural school children whose parents are financially handicapped can receive expert attention for a minimum rate. Over ninety hospitals have already affiliated. We are urging parents to give prompt attention to the notification of physical defects found by the school doctor as protective and preventive measures in the future welfare of the child. We

are urging closer cooperation between the family physician and school doctor; we are urging the former to stimulate interest in the homes into which he goes to early and periodic attention to the health of their children. We are putting into use this coming year a new health syllabus which will provide for definite health teaching in every grade, beginning with the kindergarten. Health efforts will receive as much rating on the school reports as any other subject. In this way we believe we shall get closer home interest and cooperation. We are urging our medical inspectors, nurses, and teachers to greater interest and care in school health work. We are urging a Department of Health Education in our normal schools directed by women physicians; the consolidation of rural schools, better buildings and equipment, more careful sanitary supervision in an endeavor to make the schools places where boys and girls go to improve in health. In fact, we are endeavoring to build up a constructive health program looking forward to the time when the child will enter school physically fit, his corrective needs cared for, his health habits formed, his bill of health clean.

### Constructive Health Program

No one can work with children without realizing his obligation and the seriousness of the work. Since this work started, the attitude of people regarding it has radically changed. They are now asking for school health service. The vital need is the educational side of it. "Health First" must become our slogan—keeping well—not getting well. Teaching boys and girls health laws, how to live wholesomely, should be a large part of the work of the doctor and teacher of today.

Just a word on the subject of hygiene, personal, general, and special. Hygiene should be the basic subject from which all other subjects should radiate. Many public school boys and girls of today are being cheated out of their birthright. When we realize the large percentage of children who leave school at 14, after the 5th grade is passed, we have failed lamentably in our obligations to them in connection with health education. The great obligation of arranging practical courses in hygiene giving children at least a good working knowledge of their bodies, how to care for and keep them in health after they go out into the world to work, is most apparent.

In summary, every boy and girl before leaving school has the right to knowledge concerning the following:

- (1) The structure, function, hygiene, uses and care of their bodies;
- (2) the meaning of marriage, homemaking, the responsibility of parenthood, and the duty of right living;
- (3) knowledge of the most prevalent contagious diseases; the many means of communication and how to protect themselves against these;
- (4) knowledge of the normal phenomenon of adolescence and of a healthy body, of clean thinking, and good companionship.

In conclusion, I believe school health work is particularly adapted to general physicians by reason of their natural fitness, careful attention to details, and the close relationship and response which they are especially able to get with and from children. Strange as it may seem, there are not ten women physicians doing this work in the state.

In our private work some of us have not always recognized the importance of emphasizing health habits, I feel, but in the future the health viewpoint is the one which must be taught. I do not believe we can put over our message or fulfill our highest obligation until we do this. We should endeavor also as far as possible to embody and radiate health personally. We should practice what we preach; the doctor should be a health teacher—the health director of those he endeavors to serve.

It is strange that preventive measures were not more emphasized formerly, even in our medical schools. The day is fast coming when prevention will be emphasized and the young doctor will be imbued with the health viewpoint. Some of us have waited half our lives before acquiring this viewpoint but to those of us who have attained this new vision of our profession it has opened a new world.

A set of rules with instructions for avoiding almost every variety of accident in the feature of the "safety" course which has been installed as a regular part of the curriculum of St. Louis public schools. The work also includes committees of children who formulate their own plans for adding to the program and details pupils to guard particularly dangerous street crossings.

The success of this plan was demonstrated when, after being put in operation in 1918, it was abandoned in 1919, and as a result the fatalities among children of school age jumped from 36 to 49. The children are taught that the safety of others is also their concern and are placed at crossings to help smaller children across.

# Children's Play in Hospitals

TO keep the mind of the adult patient occupied while in the hospital has been proved to hasten recovery, and in like manner the amusement of children who are forced to spend a greater or less time within hospital walls has come to be a profession. The children's ward of the Massachusetts General Hospital, Boston, exemplifies one of the notable successes of this work. Under the direction of a woman trained in kindergarten and Montessori methods and in story telling in libraries and settlements, these children from the tiny babies to the fourteen and fifteen year olds are given recreations suitable to their mentality and interests.

Isabelle L. Whittier is the "play lady" in this hospital. Even small babies suffer ennui when left to convalesce for hours in their cribs, Miss Whittier believes. These she stimulates by tying to their beds six colored worsted balls which swing back and forth. Besides amusing the child they give him his first lesson in concentration. Children of two years are delighted with cylindrical wooden insets, three sets of which can be fitted into holes in wooden bars. This taxes the little patients' ingenuity and keeps them interested for hours.

Children four, five and six years old like to play memory games. From a tiny chest of drawers the blind-folded child draws out a piece of linen, cotton, silk, or velvet, feels it and tells the name of the material.

their amusements are therefore of greater scope; they are also more difficult to entertain for individual tastes begin to assert themselves. Nature study, on the whole, is a common interest. Bird charts help them to identify birds they have seen.

Some of the children enjoy handicraft and make from old cigar boxes attractive lacquered work boxes.

Parties are as fascinating to the

Montessori cylindrical wooden insets enthrall the attention of the two-year-old who often spends hours fitting the pieces into the holes.

bed-ridden child as to the active youngster able to run about. At these parties Miss Whittier brings out her magic chair, a dainty gilded thing with a music box in the seat. The legend is that when a good child sits on the fairy chair a tune plays. One by one the children wrapped in their blankets are placed on the chair. There is a slight pause before the music starts and each child perforce recalls any misdeeds during the month. The look of suspense is fol-

too noisy. Kindergarten methods require too much supervision to be of great use in the opinion of Miss Whittier, but the Montessori methods have proved successful, for the reason that the children can teach themselves. There is still a lack of occupations for older boys.

Of the value of Miss Whittier's work from a medical standpoint, Fritz B. Talbot, Chief of the Children's Medical Service, Massachusetts General Hospital, says: "Miss Whittier has filled the lacking gap in our ward and the results have been beyond my expectations. \* \* \* Miss Whittier's cooperation in amusing and educating the children has been of more than academic and humanitarian interest because it has been of real therapeutic value and has hastened the cure of the child. I feel that there is a place for such work as Miss Whittier carries out in all hospital wards for children."

## An English Nursery Hotel

A nursery hotel for children whose parents are facing a personal or domestic crisis is maintained at Oxfordshire, England, reports *The Lancet*. The house, located on a high sunny hill, is surrounded by two acres of garden. Rigid institutional lines have given way to a homelike atmosphere in the large airy rooms.

The physical well being of the children is adequately protected. A med-

Silk or velvet— which? is an exciting game for little patients. This educates their sense of touch as well as giving them the thrill of mystery.

Even small babies get bored looking at the ceiling. Colored worsted balls stimulate their interest and give them their first lesson in concentration.

By means of the Montessori dressing frames the children are taught how to dress themselves.

Children from eight to fourteen are interested in a variety of things and

followed by a gasp of joy when the music starts.

The recreational work for hospital children is still undeveloped. Many games have to be discarded as being

ical officer attached to the hotel pays fortnightly routine visits. Children convalescent from infectious diseases are denied admittance while all entrants are isolated for a day or two.

# Prevention of Deformities in Children

BY JACOB SOBEL, M.D., ASSISTANT DIRECTOR, BUREAU OF CHILD HYGIENE, NEW YORK DEPARTMENT OF HEALTH, NEW YORK CITY.

PREVENTION of deformities is to orthopedic surgery what prevention of disease is to public medicine and health. In either case it is better to be careful than sorry. The prevention of crippled children should begin before birth by proper care, diet, and hygiene of the mother, and by the avoidance of accidents and injuries especially to the abdominal wall. Injuries to the child at birth which occur generally in the cases of long, difficult, instrumental, and complicated labor, can often be prevented by a careful selection of a properly trained and qualified attendant. These injuries may affect the brain, spinal cord, nerves, muscles, bones, joints, and other parts of the child, and cause weakness and paralysis of the extremities, with various kinds of deformities. Some of these injuries cause mental deficiency, spastic paralysis, or permanent deformities. The after-results of birth accidents vary in kind and degree from the very mild to the most serious, incapacitating, and, sometimes, hopeless.

Women who engage midwives should insist upon medical advice and care in the event of abnormal labor. Birth paralysis, not caused by brain or spinal injury or disease, in other words that is due to pressure upon or stretching of nerves, often responds promptly to efficient treatment. All injuries at birth call for immediate care, as delay may result in permanent incapacity and disfigurement.

Rickets, which so often results in deformities such as knock knees or bow legs, or other curvature of the long bones or spine may be prevented by suitable and sufficient diet, proper hygiene and surroundings, fresh air and sunlight, and the use of cod liver oil. This disease is more common among the Italians and the Negroes.

Toward the end of the first year children require "careful watching." They are always on the move at this age, and falling out of bed, the carriage or high chair may be followed by serious injury or deformity.

Then we have the congenital deformities, congenital dislocation of the hips — one or both sides — congenital club feet and hands, webbed fingers or toes, supernumary fingers or toes, short arms or limbs,

amputation (intrauterine) of fingers and toes, and many others. Some of these are curable by early operation.

After the child begins to walk, any evidence of sudden or persistent pain, limp, stiffness, limitation of motion in the limbs or spine, or muscle spasm should be looked upon with suspicion. More attention should be given by parents and physicians to complaints of "growing pains," for many sins of omission have been committed in their name. Tuberculous disease of the hip, knee, or other joints, and of the spine often dates its onset from an apparently insignificant fall or blow, which was sufficient to "light up" a dormant tuberculous process, particularly in children who were malnourished.

The prevention of deformities resulting from infantile paralysis is largely a matter of preventing the disease itself, by quarantine and isolation of those affected, avoidance of crowds, and the observance of personal and community cleanliness and hygiene during the prevalence of the disease. Proper care of the disease in the acute stage by rest, position, and support; and the institution of massage, exercise, and mechanical support at the proper time after the acute stage will help to prevent or minimize some of the deformities which are likely to result. The after effects of this disease often depend upon the severity and dosage of the infection and the amount of involvement in the spinal cord. This latter is unfortunately often beyond our control.

Deformities following disease or injuries to the brain and spinal cord are in proportion to the areas involved and are usually permanent. Occasionally mechanical or operative correction is possible. Prevention here is practically the prevention of the disease itself.

Pain or swelling of any joint, following or during the course of the contagious or respiratory diseases of childhood is often the forerunner of serious disease and deformity and requires prompt medical treatment. Enlarged tonsils, decayed teeth, and other foci of infection often cause joint involvement with deformity, while the social diseases claim their share of serious joint and bone diseases. Foci of infection should be re-

moved, and personal and community control of social disease will prevent many from becoming crippled.

In early childhood, proper posture, carriage, and breathing exercises, avoidance of awkward positions, of slouching walks, and of carrying heavy books or packages too long on one side of the body will often prevent round or stoop shoulders and spinal curvature.

Physical training and calisthenics are excellent preventives. Most children are perpetual motion machines and are always ready for play. Properly regulated games—swimming, and athletic sports are beneficial while "horse play" not infrequently causes accidents and disastrous results.

Avoidance of undue exposure, dry feet, proper diet, removal of decayed teeth, and of abnormal or diseased tonsils, and the observance of oral hygiene will prevent rheumatic joint involvements. General prevention measures require that all wounds, cuts, bruises, and burns be given immediate attention to prevent infection. Existing infected wounds should be incised and drained. Fractures should be set immediately and dislocations reduced.

Another phase of prevention consists in early treatment of deformities to limit their extension. The earlier in life a deformity is detected and corrected, either by mechanical or operative means, the better the chance of ultimate success. This is particularly true of congenital dislocation of the hip in which the age of selection is between three and six years, and of congenital club feet, in which the bloodless operation is most successful between one to three years of age.

When we realize that many of the existing deformities of children could have been prevented or certainly lessened in severity, an appeal for extension of preventive orthopedics is worth while.

Two recent publications of the Department of the Interior, Bureau of Education, dealing with problems of rural schools are "Home Economics in Rural Schools," Home Economics Circular No. 13, and "Modern Equipment for One-Teacher Schools," Rural School Leaflet No. 3.

# KOTEX

## For travel comfort, take Kotex along

**W**OMEN who can travel in comfort and with peace of mind have mastered an art. The secret is careful choice of equipment. With Kotex in the traveling bag a most difficult problem *solves itself*, as these remarkable sanitary pads are easily disposed of, more absorbent, sanitary and economical.

Each box contains simple directions for disposing of Kotex.

It is easy to buy Kotex without embarrassment as one need only say, "A box of Kotex." They are sold wherever women trade—in dry-goods, drug, and department stores. All over the United States.

Traveling or at home, Kotex is almost indispensable. Keep Kotex always on hand—ask for them by name.

Cellucotton Products Co., 166 W. Jackson Boul., Chicago  
51 Chambers Street, New York :: Factories: Neenah, Wis.

*Regular Size, 12 for 60c*  
*Hospital Size, 6 for 45c*

Sample of either size free on request.

Kotex vending machines are being installed in women's rest rooms everywhere—hotels, office buildings, restaurants, theatres and other places from which may be obtained one Kotex with two safety pins, for 10 cents.

**INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX**

## Shrine Children's Hospital at St. Louis

**A**FTER thorough studies of similar institutions, and consultation with Dr. Nathaniel Allison, President of the American Orthopedic Association, the architect, William B. Ittner, has conceived and developed plans for the Shrine Crippled Children's Hospital in St. Louis which contemplate an institution of social service and orthopedic research that will be the most complete of its kind in the country.

The site selected for the Hospital has a frontage of 380 feet on Kingshighway, and an average depth of 336 feet. It lies south of the Washington University Medical School—one of the buildings of the Barnes Hospital group overlooking Forest Park. A subterranean tunnel will connect the hospital with a central power plant of the Barnes group.

The new hospital will be made up of a three story administration building placed diagonally facing the corner; and two ward buildings, each two stories high, facing west and south respectively will connect closely with this central unit. This arrangement affords desirable light and air for the ward buildings and makes an interesting architectural group. While the Shrine Hospital will differ in style from the Barnes group, care was taken that the new building should strike a harmonious note with the old.

The first floor of the administration building contains an admitting ward reached from the main approach, and consists of five rooms to receive one patient each, an examination room, a reception room, a room for the head nurse, and the necessary utility rooms. This floor also contains the

main administration offices, being made up of the business office, superintendent's and secretary's offices, and a reception room for visitors. In the connecting wings between the administration and ward buildings are two elevators and stairways.

The first and second floors of each ward building contain the main wards to accommodate twenty beds respectively, making a total of 80 ward beds. Each ward is divided by glass partitions into three cubicals. Dining rooms and sun rooms adjoin each main ward. Across the corridor from each sun room are two wards for individual cases, and across from each dining room is a diet kitchen. The necessary utility rooms, toilets, baths, and surgical dressing rooms correlate with these wards.

The second floor of the administration building contains the clinical, x-ray, and photo gallery with the essential store and filing rooms, the rooms of the staff, consisting of a resident physician, two resident assistants, and two interns.

The third floor consists of the operating suite which includes three operating rooms, one being equipped with a spectators' amphitheatre. Along with these three rooms are the necessary rooms for anesthetic, sterilizing, utility, surgeons, and nurses.

The ground floor of the administration building contains the main kitchen and the dining room for the staff and help. The ground floors of the ward buildings contain rooms for soiled and clean linen, sewing, cutting, mattress sterilizing, patients' clothes, morgue, drugs, massage, carpenter shop, orthopedic shop, uphol-

ster shop, barber shop, and general storage.

The new hospital will be built and equipped at an approximate cost of \$425,000.00.

That the day of the blind baby is passing, banishing with it the most prolific cause of blindness in children, ophthalmia neonatorum, is indicated in a summary of state laws and rulings relating to the prevention of blindness from babies' sore eyes, Publication No. 9, recently issued at headquarters of the National Committee For the Prevention of Blindness in the Russell Sage Foundation Building, New York.

The summary shows that in 44 states the reporting of babies' sore eyes to the local health officer or to a physician is now compulsory. The only states in which such legislation has not yet been enacted are Arizona, Nevada, Texas, and Wyoming. The use of a prophylactic, "drops," in the eyes of infants at birth is required by law of physicians and midwives in 24 states, by physicians only in two states, and by midwives and attendants only in two states. Free prophylactic outfits are distributed in 28 states and popular educational leaflets on the prevention of infantile blindness are distributed by state departments of health in 35 states. In only 17 states, however, are births reported early enough to be of assistance in prevention of blindness work.

The use of anti-diphtheritic serum in massive doses is receiving considerable attention in France and Italy reports M. P. Lereboullet in *Paris Médicale*.

The Shrine Crippled Children's Hospital at St. Louis is one of five being erected by the order in various large cities in the United States and Canada.

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank and natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

## Good Water Polluted by Bad Handling

Certified water of satisfactory quality and safety may be so handled in its delivery and storage aboard a vessel as to render it unfit and unsafe for consumption, says the U. S. Public Health Service in a recent report. For instance, the methods used by passenger vessels operating on the Ohio and Mississippi Rivers in the summer of 1921 frequently result in contamination of the water. On the Great Lakes, on the other hand, the methods used were generally satisfactory and the results of the bacteriological analyses showed much lower counts. By law, drinking water on vessels engaged in interstate traffic must be obtained from certified sources ashore or must be purified by treatment aboard "by an approved method."

Facilities for conveying the drinking water aboard vessels along the rivers have not always been unsatisfactory. At Louisville, Cincinnati, Evansville, Huntington, Pittsburgh and other river ports, certified water is available but in 1921 was carted from the nearest hydrant in kegs or barrels. The report recommends that hydrants to public water supplies be placed on the piers at places convenient for delivery through hose. The hose so used should be carefully protected from contamination from the river water and other sources and should be used for no other purpose. Where the river level is subject to marked changes, a water pipe should be run down the incline of the landing. City hydrants, properly protected, should be placed on it at about each fifteen feet of vertical rise in the landing. Preliminary steps to do this are now being taken at all five of the cities named above.

## Student Health Service and Public Health

There is no such detachment between the student health service and the student body as exists between the average health department and the community served. Whether he is interested to do so or not, the student must undergo the routine preliminary physical inventory and his subsequent assignments in hygiene give an added value to the results of his physical examination. Certification in health becomes a matter of pride, perhaps a necessity and corrective measures a prescribed duty.

The sympathetic attitude of mind

is one contribution to public health which Dr. J. Howard Beard emphasizes in a recent issue of the *Journal* of the American Medical Association as an important contribution of student health services to public health. Another is the public health insurance involved in early discovery and correction of incipient disorders perhaps unsuspected by the people affected. The successful application of corrective measures is well calculated to produce a higher appreciation of the relation of physical and mental adaptation to successful careers and to efficiency in occupation.

The findings of the physical examinations among students are of the greatest value in public health, for they are always subject to "follow-

up" work. Dr. Beard suggests also, in the interest of analytical studies, that a "follow-back" should be adopted as well so that generalizations may be made on the correlated findings of dentist, aurist, oculist, laryngologist, clinician, and surgeon which can later be applied to discerning the cause of the so-called degenerative diseases and the influence of occupation and habits in relation to them. As the influence of such services permeate the masses, sanitary advancement will be supported by a dynamic public opinion, and departments of health will no longer need to devote such a disproportionate amount of time, energy, and money toward health instruction of the masses.

## Nursing New York City's Poor\*

IN THE heart of New York's lower east side, in that conglomerate melting pot, a humane, health-promoting agency is conducted which Prof. William Welsh of Johns Hopkins has called one of the real American contributions to the progress of the world. This is the Visiting Nurse Service of the Henry Street Settlement, started more than thirty years ago by Miss Lillian D. Wald and her colleague, Miss Mary M. Brewster, with headquarters on the top story of a tenement house and with no greater staff than their own two pair of hands.

Today, in addition to the headquarters at the Henry Street Settlement, the Visiting Nurse Service, under the

generalship of Miss Wald, and the direct command of Miss Annie W. Goodrich, maintains a public health service through which 230 trained nurses in twenty-two centers bring comfort, healing and the message of healthful living to the homes of Manhattan, Richmond and the Bronx. The work begun from the top floor of the tenement has been developed into the many highly specialized branches of public nursing now covering the United States.

To illustrate the inclusiveness of all races, creeds, colors and classes ministered to by the Visiting Nurse Service, Miss Wald tells the story of a

\*By Rose Rossner in New York Times.

Practical demonstrations of how to bathe a baby, how to prepare the food, and other essentials of infant and child care are daily given by the 250 nurses who, under the supervision of the Henry Street Settlement nursing service, care for hundreds of patients a year in the crowded sections of New York City.

# A New Idea in Shoes that is 2000 years old

**I**N the days of old Rome the people wore sandals, designed primarily to support the foot as Nature requires. The sandal afforded a foot-length support, just like going "bare-footed." There is no record of foot weakness or discomfort in those early days.

But Civilization, in its eagerness to secure more stylish apparel, adopted the heel. This marked the end of the natural foot-length support. The foot arch was allowed to sag, subject to a constant strain. Today ninety percent of all women suffer with their feet largely because the arch is not properly supported as Nature planned.

The Arch Preserver Shoe—a new idea in shoes that is 2,000 years old—has revived the sandal comfort and healthfulness. Its concealed, built-in arch bridge gives the foot the same support as when walking "barefooted"—keeps the arch from sagging while the heel is raised from the ground—in the smartest shoes that Fashion knows.

Nature plans that the foot rest on heel, ball and outside arch.

Civilization demands that heel and arch be raised.

The Arch Preserver Shoe satisfies both Nature and Civilization.

The Arch Preserver Shoe is the only shoe of its kind because its distinctive construction is patented. To satisfy both Nature and Fashion you therefore must be sure that you are buying the genuine Arch Preserver. This trade-mark on the sole and lining is your guarantee.

Nurses of the Henry Street Settlement Visiting Nurse Service round up their patients and take them to the Red Cross health center—with which they co-operate in the community—where babies are weighed, proper diets demonstrated and other preventive as well as curative measures explained to the eager mothers and children. The Henry Street nurses cover an immense area in their daily visits through the three largest boroughs of New York.

French major who came to inspect the centers. When asked which of the patients he would like to visit in their homes with the nurses, he requested to see the Spanish-speaking Turks. Upon looking up the records it was found that two such families were being treated for influenza—so the major had his wish.

So far-reaching a city influence has this service become that it has been found necessary to acquire a centralized headquarters. A large building, the gift of Mrs. Jacob H. Schiff in memory of her husband, is being erected at Park Avenue and Fortieth Street for this purpose. It is for the carrying on of these enlarged facilities that a plea for contributions amounting to \$1,000,000 has been sent out by the committee in charge.

In her book, "The House on Henry Street," Miss Wald has described the beginning and struggles of this institution:

A sick woman in a squalid tenement so wretched and so pitiful that in all the years since I have not seen anything more appealing, determined me, within half an hour, to live on the east side, after I had spent two years in a New York training school for nurses.

The lower east side then reflected the popular indifference—it almost seemed contempt—for the living conditions of a huge population. And the possibility of improvement seemed, when my inexperience was started into thought, the more remote because of the dumb acceptance of these conditions by the east side.

Remembering the families who

came to visit patients in the wards, I outlined a course of instruction in home nursing adapted to their needs, and gave it in an old building in Henry Street, then used as a technical school and now part of the settlement.

From the school-room where I had been giving a lesson in bed-making, a little girl led me one drizzling March morning. She had told me of her sick mother, and gathering from her incoherent account that a child had been born, I caught up the paraphernalia of the bed-making lesson and carried it with me.

All the maladjustments of our social and economic relations seemed epitomized in this brief journey and what was found at the end of it. The family to which the child led me was neither criminal nor vicious. Although the husband was a cripple, one of those who stand on the street corners exhibiting deformities to enlist compassion, and masking the begging of alms by the pretense of selling; although the family of seven shared their two rooms with boarders, and although the sick woman lay on a wretched, unclean bed, soiled with a hemorrhage two days old, they were not degraded human beings, judged by any measure of moral values.

In fact, it was very plain that they were sensitive to their condition, and when at the end of my ministrations they kissed my hands (those who have undergone similar experience will, I am sure, understand), it would have been some solace if by any conviction of the moral unworthiness of the family I could have defended myself as a part of society which permitted such conditions to exist. Indeed, my subsequent acquaintance with them, revealed the fact that, miserable as their state was, they were not without ideals for the family life and for

society, of which they were so unloved and unlovely a part.

That morning's experience was a baptism of fire. Deserted were the laboratory and the academic work of the college. I never returned to them. On my way from the sick-room to my comfortable student quarters my mind was intent upon my own responsibility. To my inexperience it seemed certain that conditions such as these were allowed because people did not know, and for me there was a challenge to know and to tell. When early morning found me still awake, my naive conviction remained that if people knew things—and "things" meant everything implied in the condition of this family—such horrors would cease to exist, and I rejoiced that I had had a training in the care of the sick that in itself would give me an organic relationship to the neighborhood in which this awakening had come. Afterward, when I sought guidance, I found that in New York the visiting (or district) nurse was accessible only through sectarian organizations or the free dispensary.

The established system of private nursing; that the nurse should be as ready to respond to calls from the people themselves as to calls from physicians; that she should accept calls from all physicians, and with no more red tape or formality than if she were to remain with one patient continuously.

We decided that fees should be charged when people could pay. Our plan, we reasoned, was analogous to the custom of "private" hospitals, which give free treatment or charge according to the resources of the ward patients. Both private hospitals and visiting nursing are thereby lifted out of "charity" as comprehended by the people.

The public which has no need of our service—those wealthy men and women who by contributing large sums and small can make the further growth of our work so much easier—has so long regarded the visiting nurse service a lower east side activity that it is a problem how to make them realize the extent of our work, said Miss Wald. Statistics show that in the Henry Street center the Visiting Nurse Service takes care of a population of 216,743, equal to the population of Akron, Ohio, but the Bronx centers take care of a population equal to that of Boston, 748,060; the Melrose and Morningside centres care for a population which exceeds that of Washington, 523,000; the Chelsea, Greenwich and Hamilton centres combined minister to a population that almost equals Kansas City, 312,066; the Kips Bay, Longacre, Tremont and Union centers combined operate in an area double that of New Haven; the population of the Morris Avenue and Stuyvesant centers exceeds that of Atlanta, Ga., 213,340; the Seventy-ninth Street center takes care of a population almost as large as that of Portland, Ore., 271,741, and the Staten Island center service protects a population equal to that of Albany.

Last year 38,693 visits made to 10,257 patients in moderate circum-

## Weak Arch and Flatfoot —

that need mechanical correction are very prevalent and frequently are associated with painful heel, callouses on sole, fatigue, nervousness, neurasthenia, physical exhaustion and rheumatic tendencies. Heavy people and those who are constantly on their feet and whose occupation requires them to assume a posture conducive to the weakening of the leg and foot muscles are usually victims of these complaints. The corrective treatment is simple. Remove predisposing causes such as short hosiery, improperly fitted or constructed shoes and have patient fitted to

### *Dr Scholl's* *Corrective Foot Appliances*

which are scientifically constructed to relieve muscular and ligamentous strain, remove abnormal pressure and restore foot to usefulness. There are distinct types of appliances for each condition. All quickly and easily adjusted to any degree of elevation or curvature, assuring the physician dependable results.

Leading shoe dealers and surgical supply houses in every locality carry Dr. Scholl's Appliances and have also been instructed in Anatomy of the Foot and the proper method of adjusting the appliances to fit both foot and shoe.

stances disproved that only the very rich and the very poor can "afford" a nurse. All that is necessary in times of sickness is to have the patient or a friend or relative telephone to the nearest service center, and in from fifteen to twenty minutes, with no further red tape, a nurse will be at the bedside of the patient, call in the aid of a physician if necessary, and visit the patient once a day thereafter, attending to his wants and needs, and leaving instructions for his care until her return the next day.

"Our greatest satisfaction," explains Miss Wald, "is that we have been able to lift the stigma of the charitable institution from the Visiting Nurse Service. The movement today is 40 per cent self-supporting. Some patients pay the full price of \$1 per visit—others pay in part—and many pay nothing at all, but that is a temporary condition. I mean that a family that is on the non-paying list one year almost invariably, with the bettering of their financial status, the next year becomes either a part-paying or a full-paying subscriber to our service."

As our plan crystallized, Miss Brewster and I were certain that a system of nursing the sick in their homes could not be firmly established unless certain fundamental social facts were recognized. We tried to imagine how loved ones for whom we might be solicitous would react were they in the place of the patients whom we hoped to serve. With time, expe-

rience and the stimulus of creative minds, our technic and administrative methods have naturally improved, but this test gave us vision to establish certain principles, whose soundness has been proved during the growth of the service.

We felt that the nursing of the sick in their homes should be undertaken seriously and adequately; that instruction should be incidental and not the primary consideration; that the etiquette, so far as doctor and patient were concerned should be analogous.

An estimate made some time ago, and since confirmed, shows that 90 per cent of sickness is cared for in homes and only 10 per cent in hospitals. The Visiting Nurse Service takes care of more people than thirteen hospitals combined could possibly take care of at the same time. It is useless to argue that if a city provides the hospitals the people when sick should go to the hospitals. The largest proportion of sickness has been and will continue to be cared for in the homes. It is the function of the Visiting Nurse Service, not only to give the sick in their homes skilled nursing care, but also instruction in personal hygiene, sanitation and the prevention of disease.

"Enthusiasm, health and common sense on the part of the nurses," according to Miss Wald, "are essential, for without the vision of the importance of their task, they could not long endure the endless stair-climbing, the weight of their bags and the strain upon their emotions."

## Dispensary Service in U. S.

THE first presentation of dispensary data by the Council on Medical Education and Hospitals of the American Medical Association is made in the *Journal of the American Medical Association* issue of August 5, 1922. The statistics are based on an extensive survey of the dispensaries, outpatient departments, clinic, and other medical institutions having to do with the care and treatment of ambulatory patients, the figures being drawn from reports received from the superintendents, medical directors, or other executives of the institutions studied. Acknowledgment is made for the valuable assistance in the survey rendered by officers of national health agencies, hospital associations, and voluntary medical organizations serving ambulatory patients. Quoting from the report:

Information is published in regard to 3,243 institutions from which reports were received and which are known to exist. Of the 3,243 dispensaries listed, 946 are outpatient departments of hospitals or independent dispensaries which provide general medical and surgical service for their patients, while 2,297 are special dispensaries, such as those for tuberculosis and venereal diseases;

mental hygiene and baby and child hygiene clinics; dispensaries of eye, ear, nose and throat and orthopedic hospitals; dispensaries connected with industrial plants, and offices and stations of the United States Public Health Service.

One of the tables published gives the distribution of general dispensaries by states. Of the 946, New York State has the largest supply, 163, followed by Pennsylvania with 136, Massachusetts with 74, California with 56, and Illinois with 48. In regard to the numbers of patients cared for, New York naturally leads with 1,182,818, followed by Pennsylvania with 537,438; Massachusetts with 268,775; California with 193,920, and Illinois with 169,872. Of the 3,872,345 patients attending the general dispensaries, 2,717,850, or 70 per cent, attended dispensaries in the fifty largest cities. In New York, of the 1,182,818 dispensary patients, 958,622, or 81 per cent., are in New York City.

Reports received from special dispensaries show that although on the average they cared for smaller numbers of patients, at the same time the patients, as a rule, made large numbers of visits. An estimate for the 2,297, based on definite reports which were received from the majority, indicates that these institutions cared for a total of 3,750,000 during the year who, during that time, made approximately 16,000,000 visits.

The total number of patients in all dispensaries during the year, therefore, was approximately 8,000,000 who, during the same time, made approximately 29,500,000 visits to those institutions.

One of the live problems relating to dispensaries is the abuse of such service by patients who are able to employ physicians. Investigation indicates that this abuse is not so extensive as has been supposed. The problem is being solved by a careful investigation of the financial status of patients, which is being done by many dispensaries through a cooperation with bureaus of charity which keep a register of the financial status of those seeking financial assistance.

Another problem is the establishment of a schedule of fees for the various services rendered by the dispensary and varying in accordance with the extent of the services rendered. A large number of dispensaries have already established such schedules, but there is no uniformity among dispensaries in the fixing of such charges. There is, also, an evident lack of justice to the patient and of economy to the dispensary in the disproportionate charges for different services in the same dispensary, such, for example, as a charge of ten dollars for roentgen-ray examination, with no charge for a Wassermann test. The next few years will doubtless see much progress in regard to the fixing of reasonable fees so that a larger proportion of the expense of conducting the dispensary can be borne by the patients.

Another problem which in recent years has been given extensive discussion is that of the pay clinics. The object of such clinics is to enable patients who cannot afford to pay the fees charged by physicians to secure satisfactory medical and surgical service at lower rates. Such clinics will be instruments of great good if they accept only such patients as are referred to them by physicians or who are found, on investigation, to be unable to pay full fees. In this way the pay clinic will work in cooperation, and not in competition, with the medical profession.

We find no record of any survey of dispensaries having been made until that by the United States Census Bureau in 1910; at that time there were only 574 including both general and special dispensaries. An estimate in 1916 placed the number at 900. The present survey gives definite information in regard to the existence of 3,243 dispensaries, not including several hundred others in regard to which there appears to be authoritative evidence regarding their existence but from which thus far it has been impossible to obtain reports. Including the latter, the total would be more than 4,000.

The increase in population in the country has had some influence on the development of outpatient dispensaries, but the chief stimulus, especially in recent years, has been the increasing popularity of the dispensary as a place to secure satisfactory medical service.

# No Growth Without Vitamines

The Bio-Chemical Laboratory of the University of Cambridge recently conducted an exhaustive investigation to determine whether the vitamines known to be present in the raw materials from which VIROL is manufactured were present in their active state in the manufactured VIROL as sold to the public. This report which fully proves the presence of the vitamines in VIROL will be sent to any medical man on application.

## Advantages of VIROL

It contains the vitamines.

It is a well balanced food.

It is easily absorbed in the most delicate conditions.

VIROL exercises a remarkable influence on growth and development. It is a food of great value for expectant and nursing mothers, in anæmia, malnutrition, and all wasting conditions.

## Coffee a Safe Stimulant

RESEARCH now being carried on by Prof. Samuel C. Prescott, professor of industrial biology and director of the scientific coffee research at the Massachusetts Institute of Technology, has led to the conclusion that coffee is a safe stimulant.

Study of the literature of coffee reveals the many varying chemical analyses of coffee, the totally opposite opinion expressed on the same points, and the necessity for revising entirely the methods of testing. The method used in the research to determine the amount of caffeine has been repeatedly tested and a standard arrived at for the purpose of determining the best methods of making the best beverage coffee possible.

The effect of caffeine is well known. For the great majority, it is merely a mild heart stimulant, increasing the power to do muscular work, and to concentrate, thereby increasing the power to do brain work. Caffeine can be taken by the vast majority of healthy adults without subsequent narcotic or depressant effect, but excessive amounts incite temporary disturbances in the central nervous system.

Experiments conducted by Professor Prescott and his assistants have shown that most persons prefer coffee which has not only *not* been brought to the boiling point, but which has been prepared at a temperature considerably below this point.

The kind of receptacle in which coffee is made has much to do with its flavor. Actual tests on a number of consumers revealed that the majority prefer coffee prepared in a glazed pot, including utensils of glass, porcelain, vitrified earthenware, or agate ware, and not brought into contact with tin, copper, aluminum, silver, or other metal. "Many of these metallic substances yield pronounced flavors when covered with an organic solution such as coffee infusion," says Professor Prescott. This flavor is particularly marked in the case of tin, tin-plate, and copper containers.

The majority of the test subjects liked coffee best prepared in the following manner: Bring the water to the boiling point, remove from the source of heat for a moment or two and then add the coffee. This brings down the actual temperature of reaction to a point below that at which the severe chemical change takes place. Do not start with water at

the temperature desired for reaction.

The filtration or drip processes yield a good coffee if made with fresh materials and with the right conditions of time, temperature, and utensils. The use of percolation processes in which the ground coffee is constantly subjected to repeated treatment with hot water, or coffee infusion, yield much less desirable results, according to the report. Long continued heating processes or those in which the coffee is actually subjected to boiling are even worse, for they bring into solution bitter or astringent substances and drive out of solution the fine aroma which can only be obtained by retaining the evanescent ethers and volatile oils.

Other important components of coffee besides caffeine are the oils, waxes and resins, and the ethereal compounds which give the delicious aroma to a properly prepared beverage coffee or to freshly roasted coffee. Though exceedingly small in quantity, the oil is important from the standpoint of aroma and taste and soon evaporates from ground coffee that is not tightly sealed. Coffee lacks the gallasannic acid type which occurs in tea leaves, oak bark, hemlock, etc.

The various kinds of water seem to have little effect on the quality of beverage coffee. Thus far the experiments have only been made with samples of New England water, including

distilled, hard, medium, and soft waters of both ground and surface origin. Results indicate that waters containing considerable amounts of alum or of chlorine as well as waters excessively high in alkali might well affect the results adversely in the preparation of coffee.

Coffee not brought to the boiling point but considerably below this has been preferred by the majority of consumers tested out. Experiments with coffee made from a temperature of 85 degrees C. (185 degrees F.), at 90-93 degrees C. (about 200 F.), and coffee made above 95 degrees below the boiling point have been compared, the lower temperature meeting with favor, while coffee which has been boiled for even a short time has met with great distaste.

Experiments thus far have shown that the best coffee is that made by filtration which produces a clear good coffee if made with fresh materials and with the right conditions of time, temperature and utensil.

The research into the physiological effect of the different elements of coffee on individuals is being carried on by Dr. Mendenhall, head of the department of physiology at Boston University. While the study is not yet complete it would appear that our notions regarding the deleterious effects of the rational use of coffee should be transferred to its abuse and to faulty methods of preparation in a metallic coffee pot rather than to the coffee itself.

Underwood & Underwood.

The belief that coffee stimulates them to greater mental and physical effort, well appreciated by these Cincinnati fire fighters flocking about the "coffee engine," is substantiated by recent coffee research at the Massachusetts Institute of Technology which has evolved a scientific method of making coffee in which all of the aroma and taste are preserved.

# IN THE ANNALS OF MEDICINE *and* BIOCHEMISTRY / / /

## they tell the value of YEAST THERAPY

*A prominent professor of  
therapeutics and doctor of  
medicine writes:*

Is an antiseptic—increases resistance to certain infections—has laxative effect—checks fermentation. “Yeast . . . is more or less of a gastrointestinal antiseptic, increases the movements of the bowels, cleans a coated tongue, stimulates the production of white corpuscles, and often seems to aid in combating various streptococcic and staphylococcic infections. Hence it is a valuable treatment for septicemia and for boils and carbuncles.

“Besides the laxative effect of yeast, it has the ability to change the flora in the intestines and to more or less check fermentation. It should be much more frequently given in illness in which there is intestinal disturbance, especially if it is associated with constipation.”

*A professor in a great  
American University  
writes:*

Rich in B-vitamin—beneficial effects. “The claim made for their use (yeast cakes) rests on a perfectly firm basis: they are rich in ‘B’ vitamin, the proteins of the yeast cake are of good quality and the cake contains no ingredients poisonous to man. Many people are reporting beneficial effects from their use.”

*A noted professor and  
author of well-known text  
books says:*

Food value of yeast—protein valuable. “The food value of yeast does not rest alone upon the vitamin present. The protein of the yeast is itself a very satisfactory type of protein so far as the nutrition of mammals is concerned. It is made use of in the tissues of man to as great an extent as is the protein of milk or meat, two of our most staple foods.”

# Objective Methods in Vocational Guidance

By B. K. HANSON, METROPOLITAN BOYS' WORK EXECUTIVE, ROTARY CLUB, NEWARK, N. J.

**D**URING the war thousands of school boys were attracted to the industrial world by high wages while many others went on farms as cadets to increase production with a result that child labor laws were in some states eliminated and, in others, the ages were lowered and the youth of our country started on its great swing away from school.

Industrial readjustment caused so many boys and young men to be thrown out of employment that they soon became a social problem, the chief difficulty being centered about the average youth of fourteen to eighteen years at the close of the war. Some effect was noted on the boys in the grades as well as the secondary schools with a result that the Government encouraged a "Stick-to-School" movement through the Department of Labor but as this was not accepted on a national scale it did not accomplish its purpose.

Rotary International believed in the fundamentals of the Stick-to-School Campaign movement and set out through one thousand or more clubs to promote a similar program, naming it a "Back-to-School Campaign," adding a vocational aspect. The favorable results during the past two years are quite apparent. Boys are interested in their future, but do not always know where they may secure advice. Rotary, with its men of diversified business experience, is in a strategic position to assume some responsibility in "helping boys to help themselves."

## The Situation Surveyed

In Newark N. J., a city of nearly one half million population with a splendid school system, a study of the high school enrollment revealed a great falling off of students during the freshman year. This was also true of those finishing elementary school. These facts were a revelation that commanded the attention of the local Rotary Club and aroused its membership to launch a city-wide "Back-to-School" campaign.

More than eight hundred boys graduated from the elementary schools in June, 1922, and through the cooperation of the Board of Education the names and addresses of these graduates were secured. A carefully prepared letter enclosing a

self-addressed postal was sent to each graduate, the letter in a vivid way pointing to the advantages of going to High School and encouraging the boy to continue his education. It also gave him the opportunity to seek an interview regarding his further education. On the postals were four questions to be answered: (1) Do you expect to enter high school? (2) If not, is it because your parents feel they cannot afford it? (3) What business or profession are you interested in? (4) Would you like an interview with a business man regarding your future? The questionnaire sent out is printed below.

The postals which were returned revealed in every case boys anxious for interviews. In checking the returned cards with the school lists, it pointed out very plainly the inter-

est with which boys from the congested districts availed themselves of the privilege, while those from the better homes failed to return the postals. This was an outstanding fact.

In assimilating the returns, boys expressing a vocational desire were directed to a business man in that vocation. A boy interested in civil engineering was booked with an engineer for an interview, etc. In this interview the interviewer was requested first to ascertain if the boy could go through high school, and then to show him in the case of engineering what an engineer's office and equipment looked like—the Transit and Level were explained and the plotting of a recent survey shown. Incidentally the boy was made to grasp that mathematics and drawing

# LOESER'S INTRAVENOUS SOLUTIONS

ACCEPTED BY THE COUNCIL

**LOESER'S INTRAVENOUS SOLUTION OF MERCURY  
OXYCYANIDE, 8 Mgs.**

A sterile, stable solution in nonsoluble glass ampoules, 5cc containing 8 mgs. ( $\frac{1}{8}$  grain) of Mercury Oxycyanide

**LOESER'S INTRAVENOUS SOLUTION OF MERCURY  
OXYCYANIDE, 12 Mgs.**

A sterile, stable solution in nonsoluble glass ampoules, 5cc containing 12 mgs. ( $\frac{1}{6}$  grain) of Mercury Oxycyanide

We offer these solutions to the medical profession as a means of carrying on intensive mercurial treatment of syphilis.

The objections to the intramuscular method, lack of uniform absorption, irritation, induration and abscesses, are overcome by the intravenous administration.

The superiority of these solutions of Mercury Oxycyanide over the intravenous administration of the so-called acid salts of mercury, bichloride, biniodide, etc., is due to the fact that they are less apt to cause irritation of the veins, a common fault of most soluble mercury compounds.

Clinical Reports, Reprints, Price List and "The Journal of Intravenous Therapy" sent to any physician on request.

**NEW YORK INTRAVENOUS LABORATORY**  
100 West 21st Street                      NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions  
for the Medical Profession Exclusively.*

are two essentials in engineering. The interviewer could then talk with the boy as to the subjects he was most proficient in while in elementary school and, if drawing and mathematics were found among his weaker subjects, stress was given this point during the interview, and he was told the necessity of mastering both subjects. Further, the boy learned it was necessary to secure a college education or its equivalent at some institution of higher learning. The cost and opportunities for working his way through were discussed and the boy thus encouraged to enter high school. This plan was carried on in all cases where interest was expressed in various vocations.

In many cases the boy told his chums of his interview and often they sought similar advice. In this way the plan reached older boys already in industry but dissatisfied with their positions, and many were given suitable advice to attend evening school to become better equipped for the business preferred.

During such interviews with boys a splendid opportunity is offered to stress health. To illustrate: a boy seventeen from a poor home in a foreign quarter of Newark showed he was troubled with adenoids. When this was called to his attention it was found that his parents could not do without his earnings for the time necessary for the operation. They did not realize the continuous colds their boy had taken the previous winter were caused from this physical condition. The interviewer called up a Rotarian physician to ascertain how an operation of this kind could best be done; soon the boy was operated on successfully at the City Clinic with the Rotarian physician on hand volunteering his services. The firm which employed the boy, when informed of the case, paid the boy's salary during the period of his treatment and convalescence.

Similar cases of carious teeth, skin disorders, smoking, late hours, the lack of cleanliness in appearance and the inculcation of health habits of sleeping with windows open, daily bath, drinking water before meals, etc., were stressed. Health hints given by a business man in a business office certainly make a greater impression on the individual than when explained in a routine way in the school room. One of the finest explanations of Vocational Guidance as far as the health is concerned was set forth in a recent article in the NATION'S HEALTH by Dr. Sidney

1. Schwab who speaks with authority on the subject of "Mental Hygiene." Mental breakdowns are clearly attributable to the selection of a trade or business not best suited to the individual's ability, thus he often sacrifices the best that is in him by plugging along in the wrong vocation. This is one way of producing the tired and dissatisfied routinist of which in America there is a vast army.

Vocational Guidance is not a new idea. It was practiced very satisfactorily in the day of Benjamin Franklin whose father on Saturdays would spend a portion of the day with his son visiting some of the commercial and industrial plants of their days. In this way, young Benjamin was able to see the types of business in this town, and very soon after chose printing as his vocation.

With the industrial and commer-

cial growth of our country, boys and young men have the same opportunities for industrial visitation only on a larger scale.

Large industrial and mercantile plants have carried vocational guidance into their business by the organization of the personnel departments which not only select the workers with care, but prescribe to them courses of study which will make them better fitted to carry on the work required of them in their respective positions.

Added to this branch of personal work, first aid, safety first, group insurance, mutual benefit associations, cooperative plans for home building, and many other phases of welfare work. The employer recognizes the value of a satisfied employee who appreciates intelligent interest and the part the employer has in his individual case.

## Schools and Vocations

ONLY within very narrow limits is it possible to predict from the presence of given endowments at an early age a predominance of similar endowments later in life. The interests especially are particularly prone to undergo complete reversal, for which reasons Otto Lipmann, in the *British Journal of Psychology*, holds that schools must aim at a diagnosis of formal endowments only. Vocational study in schools seeks first to establish the degree of individual endowment, and then to determine the specific nature of these endowments, the choice of a suitable vocation being among those considered well within the ability of the individual. The problem, however, is not so simple, for the interest in a given occupation may be quite disproportionate to productive ability in that line. The interest in a majority of cases is determined by the purely material aspects of a vocation. With the actual nature of the work young people are usually quite unfamiliar.

With reference to formal endowments the customary division is made into (1) higher, (2) middle, and (3) lower vocations, as determined by the vocation in which the workers act "freely," by virtue of the intelligence or imagination not being hampered by fixed rules and definite limits. Freedom is greater in learned and artistic than in industrial occupations. Men capable of working along individual lines should avoid vocations in which the nature of the work requires

that it be prescribed in all its details.

The activities themselves may be divided into productive, reproductive, and receptive types. Temperaments which admit of easy automatizations may be fitted for work of a fixed and definite kind, and general intelligence and adaptability, according to Lipmann, are of greater moment than specific abilities. He suggests the advantage of work schools to bridge the gap between the school which has permitted no opportunity to observe the behavior of the pupils with reference to various handicrafts and commercial occupations.

Under no circumstances is the school itself to undertake vocational advice for the reason that the results of tests are to be viewed in the light of the psychological requirements of the various trades and professions. Nor is any vocation to be determined upon even on the basis of special adaptabilities without bearing in mind the economic factors involved, and future opportunities. Qualities also determine the selection of a suitable occupation. A pupil adapted to solitary and individual work may satisfactorily be apprenticed to a private craftsman, but one of a social nature may do better in a factory. The schools should, however, unflinchingly impress upon pupils the importance of vocational advice, for in no instance is so momentous a decision to be left to chance circumstances or to a passing mood.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

## Surgical Operations by Fedor Krause

In the words of Albert Ehrenfried who has translated into English and edited the six volume textbook of "Surgical Operation" by Fedor Krause and Emil Heymann, "the book is primarily a textbook of operative surgery. Its purpose is to tell how to operate and it fulfills this purpose with all the exact detail for which the German mind is noted, interpreted by a wealth of illustrations surpassing any textbook I know of."

The authors approach their subject in a novel way by the presentation and discussion of actual cases which are carefully followed from the beginning through the operative treatment to the end results.

Only Volumes 1 and 2 have so far been received by the reviewer. Volume 1 deals with general surgical technic and with surgery of the head. Volume 2 continues with the surgery of the head and covers brain surgery.

The illustrations are very beautiful and cover almost every step of the operations described. Most of the illustrations are colored, the majority in two color. This brings out the anatomical field with much greater clearness than the usual pen and ink or wash drawing.

The insertion of the clinical notes adds without doubt to the interest of the book but detracts greatly from its practical usefulness as a text.

Rebman Company, New York, 1917.

## Report of U. S. Public Health Service

The report of the United States Public Health Service for the year 1921 outlines the work of the department as the largest Federal agency for the protection of public health. Its chief functions are the prevention of the introduction of diseases in the United States; the investigation of diseases of man and stream pollution; the supervision and control of the biologic products; public health education; and the operation of hospital service for various groups including disabled ex-service men and women.

In the division of scientific research, special emphasis has been laid upon rural health demonstrations in cooperation with the states. Researches into child hygiene, industrial sanitation, and particular diseases have been carried on. The hospital service had to expand rapidly to meet the emergency following the signing of the Armistice. Since the beginning

of the work the Service examined some 1,000,000 applicants for compensation, furnished hospital care to 200,000 patients, dispensing treatment to 1,300,000 patients, dental service to 75,000 patients, and occupational therapy to 10,000 patients per week.

Foreign and domestic quarantine regulations are largely for the suppression or prevention of epidemic diseases. The rat campaigns, the reporting of communicable diseases, the supervision of water supplies are all a part of a general program. Sanitation and medical assistance in the national parks were established after investigations by Service engineers. The installation of garbage cans, the testing of water supplies, and the disinfection of privy vaults are of great importance in such universal pleasure spots. Data concerning the type and prevalence of diseases in the parks will be collected.

The matter of supervising the transportation of diseased persons on common carriers in interstate traffic and the transportation of articles from disease infected localities with attention to the sanitary conditions on carriers has been controlled as far as possible under interstate quarantine regulations but there is room for the development of much more effective work here.

## Shock Exhaustion and Restoration

A remarkable monograph by Dr. George W. Crile is brought out under the title, "A Physical Interpretation of Shock Exhaustion and Restoration." It should be carefully read by all physicians, whether they are practicing surgery, medicine, or any of the specialties. Crile has brought together here his vast experimental work, and has indicated the clinical application of the investigations which he has conducted for years. He gives his ideas about surgical treatment and also, one might say, his philosophy of surgery. Since Crile is a truly great surgeon, his conception about surgery should be of extreme importance to everyone.

A careful critical analysis of this book is not possible in the limited space. It can be stated, however, that there are many who doubt the importance of the results claimed by Crile as regards changes in nerve and other cells as the result of exhaustion. By some the method which he uses to distinguish between a rested cell and an exhaust cell, differentiation by means of the staining reac-

tion of these cells after they have been fixed, is considered a crude and inaccurate method. This criticism also appears to the reviewer as being justifiable. Nevertheless, this is only one phase of Crile's work, and his investigations reach much further than this.

There is one thing which stands out prominently, whether the theoretical conclusions which Crile deducts from his experimental work are correct or not. The practical methods which these have given rise to in the actual treatment of surgical patients, are undoubtedly correct. Crile's system for preparing a patient for operation and for treatment after operation is the most extensive one which has been reported, and is the most logical and common sense system known to us. Undoubtedly more care is given these matters in Crile's hospital than in most others, since many hospitals are lamentably or even criminally negligent of these supremely important matters. It is hoped that many surgeons will follow Crile in his practice of treating patients, whether they follow him in his theories or not.

Oxford Medical Press, London, 1921.

## Graphic Methods in Heart Disease

Of late many methods have been added for the study of heart conditions. While nearly every textbook on physiology contains a description of some instruments used for the study of the heart mechanism, the average physician has no access to a practical book on methods by which heart disturbances can be detected. John Hay's "Graphic Methods in Heart Disease," therefore, supplies a distinct want in medical literature. Of course it is not expected that every physician will make use of the instruments and records described in this book.

Oxford University Press, New York, 1921.

## Transactions of the American Pediatric Society

The Transactions of the American Pediatric Society usually contain the latest word in Pediatrics. The volume for 1921, edited by Joseph Brennemann, is no exception to the rule. Some of the more advanced work in pediatrics done during 1921 has been incorporated in this volume. It was ably edited by Dr. Joseph Brennemann, of Chicago.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

## FROM THE FIELD

The twelfth annual meeting of the American Child Hygiene Association, of which Herbert C. Hoover, Secretary of Commerce, is president, met at Washington, D. C., October 12, 13, and 14. Among the speakers were Mr. Hoover, Sir Auckland Geddes, Dr. L. Emmett Holt, and Miss Elizabeth Fox of the Red Cross.

At the International Health and Safety Exposition to be held at Oakland, Cal., November 17 to 26, the field of public and private health will be presented by means of charts and lectures with special emphasis on disease prevention and health education among children.

The Colorado Tuberculosis Association, Denver, will hold a two weeks' institute on the nutritional problems of children from October 18 to November 1. Dr. Wm. R. P. Emerson of Boston, will be in charge. The Institute is being conducted especially for physicians, public health nurses, dietitians, social workers, physical education and home economics teachers.

The first National Standardized Health Exhibition was held in the Twenty-Third Regiment Armory, Brooklyn, the week of October 7. The National Health Council, the Kings County Medical Society Health Committee, the Brooklyn Chamber of Commerce Health Committee, the New York City Health Department, and the Safety Institute of America cooperated in the exhibition.

Sweeping reductions in employers' liability insurance rates, averaging 20 per cent, have been approved and promulgated by William E. Tuttle Jr., State Banking and Insurance Commissioner of New Jersey. The new rates went into effect September 1. This is the first time reductions on such a scale have been made since the Compulsory Liability Insurance law went into effect in 1917, and is the first to be based exclusively on the experience of the New Jersey Banking and Insurance Department, using figures obtained in New Jersey industries. It is estimated the saving in manufacturers' overhead costs will amount to \$1,000,000 annually.

Bringing the College of Medicine and Surgery to the University of the Philippines up to the recognized standard of class "A" colleges of this sort in the United States by revision of the college curriculum and the establishment of a central nursing school that will double the number of trained nurses graduated annually in the Philippines are two of the important measures regarding public health and the control of diseases that have come about from the work of Dr. Victor G. Heiser, Far Eastern representative of the Rockefeller Foundation, since his arrival there.

With the purchase of the former residence of R. Hall McCormick at the northwest corner of Rush and Erie streets, Chicago, by Dr. Franklin H. Martin, owner of the Surgical Publishing company, and the contemplated erection of the Dr. John B. Murphy memorial on the site between it and the American College of Surgeons, Chicago's aspiration to become the surgical center of the western hemisphere will be furthered.

Dr. Martin, who is an organizer of the American College of Surgeons and its director general, will move his company which publishes *Surgery, Gynecology, and Obstetrics* to the former McCormick residence. It is his stated intention to present the surgical journal together with its new home to the American College of Surgeons. The John B. Murphy Memorial to be erected between the two buildings will contain a memorial hall open to all medical societies, a medical library, and a museum.

Michigan is holding a series of health institutes in various parts of the state lasting from October 2 to December 2. The counties to be visited during the two month period are Montcalm, Mecosta, Clinton, and Oakland. The personnel of the newly organized institute staff consists of Dr. Frank A. Poole, lecturer and field director of the unit; Dr. Florence A. Browne, head of the infant unit; Dr. C. A. Wilson, head of the tuberculosis division; Dr. Frank Rose, head of the children's unit; Melita Hutzler, lecturer, and Lucile Moore, assistant director of the bureau of education, organizer. Three nurses will assist the clinicians.

A reward of one million dollars will be offered by the United States Government for a successful cure of tuberculosis, cancer, paralysis, epilepsy, or dementia praecox, should the bill introduced by Representative Sproul of Illinois become a law.

The Southern Medical Association will hold its sixteenth annual meeting in its birth city, Chattanooga, Tenn., Monday, Tuesday, Wednesday, and Thursday, November 13-16, 1922 under the presidency of Dr. Seale Harris, Birmingham, Ala. Dr. E. D. Wise, City Health Officer of Chattanooga, will deliver the address of welcome, which will be responded to on behalf of the Southern Medical Association by Dr. W. S. Leathers, State Health Officer of Mississippi, Jackson, Mississippi. Dr. C. C. Bass, Dean of Tulane Medical College, New Orleans, will deliver the Oration on Medicine, Dr. Hubert A. Royster, Raleigh, North Carolina, the Oration on Surgery, and Dr. S. W. Welch, State Health Officer of Alabama, Montgomery, Alabama, the Oration on Public Health.

At the joint dinner session of the section on surgery and the section on radiology Tuesday night, Dr. George W. Crile, Cleveland, Ohio, will represent the section on surgery, and Dr. George W. Holmes, Massachusetts General Hospital, Boston, the section on radiology. The committee announces that any doctor who is a member of his state and county medical society, although not a member of the Southern Medical Association, who desires to attend this meeting can have the benefit of reduced railroad rates by requesting a certificate from the Association office.

Free physical examinations were made by physicians of the state department of public health at the Illinois State Fair, under the direction of Dr. Isaac D. Rawlings. Blood pressure tests were made and registration cards with height and weight were given out. Opportunity was taken to urge annual physical examinations. At the Pageant of Progress, Chicago, 15,000 were examined.

With the end of the fiscal year the Interdepartmental Social Hygiene Board went out of existence, no appropriation for its continuation having been made. No action has been taken on the bill introduced authorizing the Department of Justice to take over the work of this board.

## CHILDREN'S SHOES

that are  
*Scientifically  
Designed*

MANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed. Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

## *Certainty of Quality Promptness of Service*

There is frequently an urgency in the requirements of a Public Health Department, Dispensary, Industrial Hospitals and Surgeons in charge of the health groups, that calls for more than ordinary cooperation on the part of the supply house. Likewise there must be a positive assurance of the quality of each and every item.

With a full appreciation of these conditions the Chemists Supply Co. seek the patronage of these groups. Intelligent service is given on every order; the quality of our product satisfies the most exacting. The various chemicals, vaccines, solutions in ampoules, drug specialties and kindred supplies used daily or in an emergency, are at all times available; in necessary quantities.

*Try us in an emergency—Your satisfaction  
will assure your routine business.*

**CHEMISTS SUPPLY CO., Inc.**

Kentucky will conduct a mental hygiene survey of inmates of penal institutions and all school children in an effort to reduce the number of criminals and defectives in the next generation. Dr. Frank O'Brien, secretary of the Louisville Society for Mental Hygiene, is secretary of the advisory committee. The National Committee for Mental Hygiene is sending six experts to cooperate in the work.

The University of Maine, Orono, and Bates College, Lewiston, gave courses in public health at their sessions the past summer.

Dr. Delos J. Bristol of Harvard University has been appointed head of the department of public health and preventive medicine recently created at the University of Minnesota.

The Pennsylvania State Health Department, through the division of restaurant hygiene, required that all persons handling food at country and local fairs undergo a physical examination and furnish health officers' certificates showing freedom from contagious disease. Seventy-two fairs, having 2,300 refreshment stands, were covered by the inspectors last summer.

Arrangements have been completed with the U. S. Public Health Service, the State Board of Health of South Carolina, and the Seaboard Air Line Railway for an extensive survey by a sanitary engineer of the lands connected with that railroad in the state, with a view to extensive health control along the entire line. The malaria survey will be continued from Andrews to the Savannah river line and thence to Jacksonville, Fla.

A large bronze memorial tablet to the memory of the officers, nurses, and enlisted men of the medical department, U. S. Army, who lost their lives during the war is to be erected in the new Army Medical School building now in course of construction at Walter Reed General Hospital, Washington, D. C. Funds for the tablet are to be raised by voluntary contributions limited to one dollar and the list of contributors is restricted to those who saw service as officers, nurses, or enlisted men of the medical department during the war. Lieut. Col. Paul C. Hutton, M.C., Office of the Surgeon-General, Washington, D. C., is in charge of the fund.

The American Red Cross announces that scholarships in a score of educational institutions are open to former members of the Army and Navy Nurse Corps, according to a decision recently made by the Trustees of the estate of the late La Verne W. Noyes, wealthy inventor and manufacturer of Chicago. The action of the Trustees, it was explained, was taken upon information supplied by the office of Major Julia Stimson, head of the Army Nurse Corps.

To determine whether any American community, with proper organization and at reasonable expense, can reduce its tuberculosis death rate to a nominal minimum, and to ascertain the proper organization and per capita costs of such undertakings applied to large cities and rural counties, the Milbank Fund has developed survey plans in consultation with a group of the most prominent experts in public health and social work, including the following: Dr. William H. Welch, Johns Hopkins University; Dr. Hermann M. Biggs, New York State Commissioner of Health; Dr. Livingston Farrand, President, Cornell University; Homer Folks, Secretary, New York State Charities Aid Association; Bailey B. Burritt, General Director, New York Association for Improving the Condition of the Poor; Dr. James Alexander Miller, President, National Tuberculosis Association; Dr. Haven Emerson, formerly Commissioner of Health, New York City; Dr. Edward R. Baldwin, Trudeau Foundation, Saranac Lake; Dr. Lawrason Brown, Director, Trudeau Sanatorium, Saranac Lake; Dr. Allen K. Krause, Editor, *American Review of Tuberculosis*; Dr. Charles J. Hatfield, Managing Director, National Tuberculosis Association; Dr. Donald B. Armstrong, Director, National Health Council; Dr. Lee K. Frankel, Vice-President, Metropolitan Life Insurance Co.; Henry S. Dennison, Dennison Manufacturing Co., Framingham, Mass.; Prof. E. R. A. Seligman, Columbia University; Prof. W. G. Wilcox, Cornell University; Dr. Louis I. Dublin, Statistician, Metropolitan Life Insurance Co.

The Fund proposes to initiate a series of not more than three demonstrations in New York state cities and counties which will assist in their operation and support. A fund of between \$300,000 and \$400,000 annually for the next five years will be available for purposes of the demonstration in various communities, the Fund announces.

An annual prize of \$25,000 to the American who makes the most notable contribution to chemical science has been offered by the Allied Chemical and Dye Corporation of New York City. The award is to be made by a committee of seven of which Dr. Edgar F. Smith, President of the American Chemical Society, is chairman. The committee members are to have no connection with the corporation.

India leads the nations in mortality with a death rate of 37.20 per thousand, according to United States Government statistics. Italy ranks fifth on the list with a rating of 10.31 per thousand males at the age of 45. Norway, Holland, Sweden, and Denmark have still better ratings. Next to Italy comes Australia; then England, Germany, Switzerland and the United States.

A contribution of \$90,000 has been made by the Rockefeller Foundation to the Commission on Hygiene of the League of Nations.

The School of Education of New York University will establish a chair of educational sociology this fall, with Prof. E. George Payne, former president of Harris Teachers' College, St. Louis, in charge. Professor Payne will institute a course in education in accident prevention at New York University in addition to his other work.

The Michigan state administrative board has authorized the Health Department to secure the personnel of a psychiatric unit in order that a scientific report of each inmate eligible for parole might be made. The per cent of men who return to prison in Michigan at least, would be greatly reduced if paroles were subject to the recommendation of such a unit.

According to a comparative study of the health of missionary families in Japan and China and a selected group in America by Wm. G. Lennox, M.D., of the University of Denver, children in Japan show a death rate far below children in China, and even below the selected group in America. The rate for the American societies in China and Japan is almost the same as for the selected group in America. The rate for Methodist ministers in America is 50 per cent above that for Methodist missionaries in China.

Your Ally  
against  
dust,

# Semdac Liquid Gloss

(A SUPERIOR POLISH)

**B**LUSTERY days of spring, scorching winds of summer, bring a continuous stream of dust into the cleanest hospital.

An authority on bacteria states that "much less than a thimbleful of such dust may contain from 900 to 160 millions of bacteria."

*Flying* dust is dangerous. For attached to dust, bacteria are transmitted with the greatest facility from place to place. Semdac Liquid Gloss is your staunch ally against bacteria because it entangles the dust in a film, *keeps it from flying*.

Semdac Liquid Gloss is pleasant to use; is odorless; saves labor in cleaning finished wood, metal and enameled surfaces; does not gum or cake; polishes as it cleans. Semdac Liquid Gloss is produced in the laboratories of the Standard Oil Company (Indiana).

Birth registration records of children born in Maryland are to be subjected to a complete test under a plan worked out by Dr. John S. Fulton, secretary of the State Department of Health, in cooperation with the Maryland League of Women Voters. Under the plan, one thousand mothers, members of the League, will request from the Department of Health certificates of the registration of the births of their children under five years of age. There is a law in the state requiring a report to the state board of health of the birth of every child, but it is believed that the figures are far from complete. The test is preparatory to the opening of the child hygiene bureau of which Dr. J. H. Mason Knox is chief.

The National Committee for Mental Hygiene recently made a mental hygiene survey of Hamilton County, Ohio, with the findings that two out of every three children coming before the juvenile court were mentally abnormal; that 75 per cent of the inmates of the jail were mental cases; that three out of every four adults, dependent on society for their support, are not in normal mental health; and that thirteen out of every hundred children in the schools deviate from the normal mentally. The establishment of a mental clinic is recommended to ameliorate these conditions. To point out to the people the need of such a clinic in Cincinnati, the Mental Hygiene Council of the Cincinnati Public Health Federation has printed a report of the year's survey of the county's mental health.

With the signing of the Johnson-Mills bill by President Harding on June 10, maritime workers other than seamen have been brought within the protection of the Workmen's Compensation Law. The measure will affect nearly half a million workers in New York State alone.

A report by the United States Public Health Service shows that an average of 8.15 days a year a person is lost through sickness or injury by the office worker in the United States. The figures on which the report was based were carefully compiled by a large Western corporation in the year ending January 31, 1921, during which it employed an average of 1,282 office employes. An exact record was kept of the hours of work lost by each person from sickness or injury, the sickness being diagnosed by the medical department or physician.

The Florida State Board of Health has issued a bulletin on Mosquitoes and Mosquito Control prepared by George W. Simons, Jr., Chief Sanitary Engineer, and George F. Mznette, Entomologist, Bureau of Entomology, U. S. Department of Agriculture.

The International Health Board of the Rockefeller Foundation has entered into a cooperative arrangement with the health organization of the League of Nations whereby for a period of five years an epidemiologic intelligence service will be maintained. The Board also set aside a sum not to exceed \$60,000 a year to effect a scheme for the international exchange of public health personnel to be conducted under the auspices of the health organization of the League. The intelligence service is expected during the five year demonstration period to prove so valuable as to become indispensable to the several governments served and to justify provision of funds for its permanent support.

Workmen's compensation in Pennsylvania totals \$5,782,658 for the first six months of 1922. There were reported 66,257 accidents during this period. Of this number 855 were fatal, 68 caused permanent disability and 65,334 ordinary disability. There were in the cases compensated 76 leg losses, 55 arm losses, 148 hand losses, 97 foot losses, and 305 eye losses. For each eye lost through industrial accident \$1,443 was awarded in compensation during the six months' period, 305 eye losses costing in compensation as much as 133 lives. The award for eye losses was twice as great as any other award for permanent injury.

A survey of building conditions in fifty large cities during the last twenty-two years has been made by Colonel Leonard P. Ayres, economist for the Cleveland Trust Company of Cleveland, Ohio. It shows that it would require the full-time efforts of the building industry for two and one-half years to make up the shortage. New York is short 2.1 years, which means that the industry would have to work at 25 per cent above normal for eight years to catch up.

The greatest indicated shortage is in Portland, Oregon, amounting to 3.5 years. Thirty-two cities have greater need of building than New York and seventeen have a smaller shortage. The most serious conditions are in the Western cities.

The National Research Council has appointed the following committee to conduct research into sex problems: Dr. Robert M. Yerkes, Dr. Walter B. Cannon, Dr. E. G. Conklin, Dr. Katharine Bement Davis, Dr. Thomas W. Salmon, Dr. Victor C. Vaughan, and Earl F. Zinn, executive secretary.

Another example of the dangers of constricting the body is found in the cases of neuritis caused by wrist watches. The tingling pain which occurs on the ulnar side of the hand results from the constriction of the dorsal cutaneous branches of the ulnar nerve against the ulna. Some of the symptoms of this condition resemble those produced by pressure on the lower trunk of the brachial plexus by a supernumerary rib.

The new law recently passed by Congress to strengthen the Harrison Antinarcotic act, establishes a Federal Narcotics Board to be composed of the heads of the State, Treasury and Commerce Departments, which is empowered to authorize the importation of such quantities of crude opium and cocoa leaves as may be found necessary for medical and other legitimate purposes. Any alien convicted of violating the act is to be deported, while for others a fine of \$5,000 or ten years' imprisonment is provided.

The Fordney Tariff bill which places an increased tariff on microscopic, optical, and other scientific instruments and the report that the Senate has refused requests by educational institutions that they be permitted to obtain scientific instruments and apparatus free of duty are decryied by the *Journal* of the American Medical Association which considers that the non-exemption of educational institutions from such tariff would be a serious blow to science and scientific medicine.

The Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, Philadelphia, has recently started the publication of a series of open letters to members of the medical profession to give them the latest facts on tuberculosis and allied diseases, based on twenty years of clinical, sociologic, and pathologic research and practical experience. Bulletin No. 1 deals with chronic bronchitis and pulmonary infections other than tuberculosis; Bulletin No. 2 will deal with tuberculosis and syphilis.

The Boston Chamber of Commerce plans to organize a New England Research Council to study the food supply and marketing problems. President K. L. Butterfield of Massachusetts College was elected chairman of the groups of agricultural colleges and the federal and state departments interested in the formation of the Council.

Twenty countries are now affiliated with the International Research Council which met at Brussels July 25 to 28. Countries represented at the Council meeting were Belgium, Canada, Denmark, France, Great Britain, Greece, Holland, Italy, Japan, Norway, Poland, Portugal, Spain, Switzerland, Sweden, Czecho-Slovakia, and the United States. Plans for the formation of an international scientific union contemplated at a previous meeting were further discussed. It was decided to keep the medical and physiological sections separate. The executive committee of five was enlarged to include a member from each unit. Officers elected were M. E. Picard, president, G. Leconte and Prof. Vitor Volterro, vice-presidents, and Dr. G. E. Hok and Sir Arthur Sebrustro, general secretaries.

An act providing for the parole of inmates of state schools for the feeble-minded has been passed by the Massachusetts legislature. The act authorizes trustees of a state school to permit any inmate of the school to leave the institution on parole for such lengths of time and on such conditions as the trustees may determine. Before granting the parole, the trustees must investigate the home into which such inmate is to go. Other conditions which may affect his welfare are also carefully investigated before the board's permission for parole is granted.

Employees of the postal service in fifty-seven of the largest cities throughout the United States in the future will receive free medical examinations whenever desired, under a plan worked out by the Post Office Department. Such examinations, it was explained, have been authorized by the Treasury Department and will be made by representatives of the United States Public Health Service at their stations in the cities designated by postal officials. The plan is to mark the beginning of a movement to provide as far as possible free medical examinations for all postal employees.

The number of babies given away in New York City through advertisements in the daily newspapers averages one a day, according to the State Charities Aid Association, which has just announced the results of a six months' study of the subject. This investigation showed that large numbers of unmarried mothers and married couples are surrendering their babies to strangers about whose morals, personality, financial standing, and standards of living they know practically nothing; that children of unknown history and family traits, who are possibly feeble-minded or tainted with disease, are being taken over by ignorant but in many cases well-meaning foster parents. This indiscriminate giving away of children works great hardships upon individual children and individual foster parents and also has the effect of discrediting intelligent home-finding work done by competent agencies. Presumably the same practice of advertising children for adoption is going on all over the country; the children thus disposed of form a small part of the number of those who without legal procedure are passed from one individual to another, the Association has discovered.

The constitutionality of the Shepard-Towner Maternity law was attacked today by the State of Massachusetts, in a petition filed in the Supreme Court of the United States asking permission to bring an original suit against Andrew Mellon, Secretary of the Treasury, the Chief of the Children's Bureau of the Department of Labor, the Surgeon General of the Public Health Service, and the Commissioner of Education, who, under the act, constitute the Board of Maternity and Infant Hygiene. This is the first attack before the court on the constitutionality of the measure. The proceeding was instituted by order of the General Court of Massachusetts, and would restrain those charged with the enforcement of the law from carrying its provisions into effect, especially by prohibiting the expenditure of any public funds. Massachusetts contended that the act was unconstitutional and void because it would impair and violate her sovereign rights and the rights of her citizens.

The response to the announcement of the correspondence course for public health nurses which will be conducted for the New York State Department of Health by New York University and Bellevue Hospital Medical College has been so enthusiastic that it will probably be necessary later to repeat the course. There have been 287 applications for enrollment in the first course of which 229 have paid the matriculation fee and have been accepted. It has been decided to close the enrollment at 250 students for the first course. Further applications will be placed on file and if the number is sufficient a second course will be given later in the year.

*Safety* publishes in its August issue a bibliography of articles dealing with elementary education in safety.

## PUBLIC HEALTH NURSING

Successful public health nursing requires a different training and a different type of individual than ordinary hospital or sick room nursing.

For this reason greater care must be exercised in the selection of public health nurses.

Aznoe's service has a clear and comprehensive idea of the requirements for public health nursing and for this reason is able to serve either the public health nurse desiring a position, or the health department or industry wishing such an individual.

Careful selective service has made Aznoe's Registry of inestimable value to both employed and employer in every case where a public health nurse, hospital nurse, institution executive, dietitian or industrial physician is desired.

An attractive booklet, giving full details of Aznoe's service will be gladly forwarded upon request.

## American Public Health Association Meeting

THE Fifty-First Annual Meeting of the American Public Health Association, held in Cleveland, October 16-19, was notable first of all from the fact that the aims and policies of the organization were fundamentally defined and clarified so as to make it primarily a professional organization of trained sanitarians. The development and standardization of the public health profession is a problem; the mobilization of popular support for the public health campaign is another.

The feeling that attention divided between these two problems was leading nowhere led at the New York meeting a year ago to the appointment of a Committee on Re-organization with Henry F. Vaughan, Health Officer of Detroit, as chairman. This committee recommended at Cleveland that "the objectives of the Association should be the preparation, study, standardization, and presentation of scientific public health procedures, and the best method by which such knowledge can be given to the public, and the expression to the public of professional opinion in regard to such procedures."

In order to maintain the authoritative position of the Association the by-laws were changed so as to differentiate between associate members (persons interested in public health), members (persons active in the service of public health), and fellows (professional health workers of at least two years standing as members of the Association, and of established professional standing—whether employed by public or private agencies or in independent private practise).

Dr. E. C. Levy, Director of Pub-

lic Welfare of Richmond, Va., was unanimously elected president for the term 1922-1923. The other officers chosen are as follows: First vice-president, Henry F. Vaughan, D.P.H., Commissioner of Health, Detroit,

Dr. E. C. Levy, Director of the Department of Public Welfare, Richmond, Va., the new President of the American Public Health Association. Dr. Levy was born in Richmond in 1868, received the degree of Doctor of Medicine from the Medical College of Virginia in 1890. He took post-graduate courses in public health under Prof. W. T. Sedgwick at the Massachusetts Institute of Technology in 1902-3 and 1903-4. In 1906 he was appointed Health Officer of Richmond and admirably administered the duties of the office till 1917. He was then commissioned as a Major in the Army Medical Corps and stationed at Camp Pike. When Richmond reorganized its city government in 1919, combining health and five other departments into a Division of Public Welfare, Dr. Levy was appointed its director.

Mich.; second vice-president, Gabriel M. Malda, M.D., Director of the National Department of Health, Mexico; third vice-president, H. L. Rockwood, M.D., Health Commissioner of Cleveland, Ohio; executive secretary, A. W. Hedrich, New York City; treasurer, Roger I. Lee, M.D., Harvard University, Cambridge, Mass.

Members of the Executive Board, elected were as follows: L. K. Frankel, Ph.D., Metropolitan Life Insurance Company, New York City; Charles J. Hastings, M.D., Health Officer, Toronto, Canada; A. J. McLaughlin, M.D., Assistant Surgeon General, U. S. P. H. S., New York City; M. P. Ravenel, M.D., Professor of Public Health, University of Missouri; Henry F. Vaughan, D.P.H., Commissioner of Health, Detroit, Mich.; C.-E. A. Winslow, Dr. P.H., Professor of Public Health, Yale School of Medicine, New Haven, Conn.

Members of the Governing Council elected were:

1923

B. L. Arms, M.D., Jacksonville, Fla.; R. S. Copeland, M.D., New York City; C. V. Craster, M.D., Newark, N. J.; S. J. Crumbine, M.D., Topeka, Kas.; Haven Emerson, M.D., New York City; Lee K. Frankel, Ph.D., New York City; W. S. Rankin, M.D., Raleigh, N. C.; P. S. Schenck, M.D., Norfolk, Va.; C. C. Slemmons, M.D., Grand Rapids, Mich.; C. E. Terry, M.D., New York City.

1924

W. A. Evans, M.D., Chicago, Ill.; C. L. Furbush, M.D., Philadelphia, Pa.; C. J. Hastings, M.D., Toronto, Ont.; F. E. Harrington, M.D., Min-

neapolis, Minn.; E. R. Kelly, M.D., Boston, Mass.; J. P. Kennedy, Atlanta, Ga.; F. X. Mahoney, M.D., Boston, Mass.; W. H. Park, M.D., New York City; L. M. Powers, M.D., Los Angeles, Cal.; C.-E. A. Winslow, Dr. P.H., New Haven, Conn.

1925

W. R. Batt, M.D., Harrisburg, Pa.; F. G. Curtis, M.D., West Newton, Mass.; W. H. Dickie, M.D., Sacramento, Cal.; L. I. Harris, M.D., New York City; James Hayne, M.D., Columbia, S. C.; A. J. McLaughlin, M.D., New York City; R. G. Perkins, M.D., Cleveland, Ohio; M. P. Revenel, M.D., Columbia, Mo.; James Roberts, M.D., Hamilton, Ont.; G. C. Ruhland, M.D., Milwaukee, Wis.

### Resolutions Adopted

The Association adopted resolutions in commemoration of the life and work of Pasteur; in favor of more adequate teaching of public health in medical schools and in elementary schools; a resolution recording "its conviction that experiments on living animals have proved of the utmost service to the public health in the past, and therefore to civilization, and are indispensable to future progress" and therefore opposing H. R. 12605; and a resolution stating that "there should be but one standard of fitness for all who desire to practice the healing art and but one channel through which persons desiring to practice that art may obtain licenses so to do." Committees were authorized on the defense of research, on public health education in medical schools, on health education in the common schools, and on the incidence and control of pneumonia.

The first general session of the Association was devoted to addresses of welcome by Dr. R. H. Bishop, Jr., former health officer of Cleveland, Ralph Perkins, director of the Department of Public Welfare, and Newton D. Baker, former Secretary of War, now President of the Cleveland Chamber of Commerce, and to the report of Dr. Vaughan's committee on re-organization. The second general session was assigned to the other major undertaking of the year, the report of the committee on municipal health department practise; and to a symposium on public health and politics. The committee on municipal health department practise, C.-E. A. Winslow, chairman, has been engaged during the past two years in a survey of the organization of the eighty-three large municipal health departments of the United States made possible by the generosity of the

Metropolitan Life Insurance Company.

The report will be published in full as a special bulletin of the United States Public Health Service during the coming winter and will include three major sections, one dealing with the work of each of the functional divisions of the health department as performed in the group of cities as a whole, a second presenting a plan for an ideal health department for a city of 100,000, and a third setting forth very briefly the status of health department practise in each of the individual cities studied. It is hoped that this report may not only bear some immediate fruit in the development of health departments but that it may also serve as the basis for continued work by the Association along the line of standardizing and advancing public health practice in the future.

In the symposium on Public Health and Politics, Dr. Matthias Nicoll Jr., and Dr. Charles J. Hastings described the success which had been attained in New York state and Toronto in enlisting by enlightened public health work a volume of popular sentiment which ensures the earnest support of the politicians, and Mrs. Maud Wood Park brought a greeting from the League of Women Voters, whose influence has already proved of material value to the cause of public health in many states as well as at Washington.

### Public Health Administration

That state medicine is inevitable if the private physician does not aggressively practice preventive medicine and the medical profession as a whole does not assist in the education of the people in matters pertaining to health was the opinion of Dr. John Dill Robertson of Chicago as expressed in the address of the chairman at the opening session of the section on Public Health Administration. The body is a machine that cannot be replaced and the obvious remedy is an annual medical examination. The private physician often takes offense at the receipt of a reference slip from the school physician. In commenting on this deplorable attitude of some members of the medical profession the speaker declared that the "public is not now and never has been interested in so-called medical ethics," and the doctor must leave his present position or the medical profession and the public will both suffer from the activities of the fake who is a real salesman.

A great diversity of ideas was ex-

pressed in the symposium on the next step for state health departments. In the opinion of Dr. Eugene R. Kelley of Boston, the most important problem now confronting the state health officer is that of making our available knowledge one hundred per cent effective. While we should not, of course, abandon the search for new facts, sufficient knowledge is now available to do many great things that now lack attention solely because they are unknown to the majority of people. New methods must be devised for the rapid spread of knowledge but autocratic methods must not be used.

Maternity and infant welfare, dental hygiene, nutrition, and mental hygiene were some of the next steps suggested in the discussion. Dr. W. S. Rankin showed that the medical profession did not suffer even financially by the elimination of the acute fatal diseases. Such a disease may take the life of an individual in childhood, in which case the physician has lost a patient, whereas on the other hand, if such conditions are in large measure eliminated the doctor then has a patient who will attain some degree of maturity. The ideal is not to eradicate all illness and put the physician out of business—obviously an impossible thing—but rather to prolong the span of life, which in no way endangers the practice of curative medicine.

Dr. Edward Martin of Harrisburg gave as his opinion that the upper third of the medical profession was composed of leaders, the middle third of those that followed the leaders, and the lower third of the self-centered; that the sanitarian must have the upper two-thirds with him and the lower third against him. Dr. Martin also urged the introduction of courses in personal hygiene into all schools and colleges.

At its second session the section on public health administration devoted itself to plans for the reduction of high mortality from acute respiratory diseases in winter. The general phases of the problem were treated by Dr. W. A. Evans of Chicago. Dr. Evans showed that the general improvement in the death rates had been due to lowering in the summer and autumn quarters while mortality in the winter and spring months has shown but a slight reduction. The speaker said that in his judgment the department of health should be represented on every zoning commission because of the need of sunlight to sterilize the dust of city streets, and that they should, furthermore.

maintain a smoke bureau, a ventilation bureau, and aid in the stimulation of winter sports. He advocated a change in the school year to a period extending from March first to the Christmas holidays. Coryza, tonsillitis and pharyngitis, epidemic influenza, and acute pneumonia were the specific diseases under discussion. The plea was for better reporting, better diagnostic laboratory facilities, more attention to the production of effective curative biological products, vaccination of the inmates of institutions, more stringent control of convalescent carriers, and abundant research on the flora of the upper respiratory tract. Dr. Henry F. Vaughn and Dr. George T. Palmer of Detroit presented a paper on the epidemiological aspects of the problem under discussion. The seriousness of the pneumonia problem, particularly in the cities, was dealt with at length and a new epidemiological classification proposed; namely, epidemic pneumonia, sequel or secondary pneumonia, and endemic pneumonia. In opening the general discussion on the subject Dr. F. L. Hoffman called attention to the great toll of pneumonia in tropical countries and incidentally to the crime of collecting bulky statistics that are never studied.

Dr. W. H. Park in a later session reported on progress in Schick testing and immunization in the school children of New York City. Favorable results and freedom from unpleasant reaction have followed the use of a toxin-antitoxin mixture much weaker than that previously employed. Dr. Herman A. Bundeson, Health Officer of Chicago, emphasized the importance of attention to the pre-school child since 93 per cent of diphtheria cases occur in children under six years of age. He urged the importance of immunizing patients after convalescence in view of the alleged frequency of second attacks. Dr. F. W. Sears of the New York State Department of Health reported the results of Schick testing and immunization in the school children of Auburn. Edgar A. Jonas, President of the Board of Directors of the Municipal Tuberculosis Sanitarium of Chicago, told of the success attained in that city by summoning physicians failing to report cases of tuberculosis before a special hearing board. This type of administrative action has proved exceedingly effective as a substitute for court procedure. The policy of the Chicago authorities, according to Mr. Jonas, is that no open cases of tu-

berculosis be allowed to remain in homes where there are children, hospitalization being enforced when the patients refuse to go to the sanitarium.

The major portion of the last section meeting was devoted to a symposium on the pasteurization of milk. Mr. Earl B. Phelps outlined the investigation that had been carried on with the support of the Borden Farm Products Company and described the three types of pasteurizing machines in common use. In the continuous type, the speaker stated that the time period was apt to be unsatisfactory since the rate of flow might not be equal in all of the pipes due to eddy currents in the flow. As a result of this action some portions of the milk might be held more than the required time and others might pass more rapidly. In the holding type this time factor is eliminated but the possibility of a leaky distributing valve introduces a grave danger. The vat type while the simplest depends largely for its effectiveness on the operation and attention that is given. Mr. William B. Marcussen described the field laboratory used in making the tests and Dr. M. J. Rosenau gave the results of the bacteriological tests insofar as indications can be judged from that portion of the tabulations that have been completed. We are well aware of the fact, Dr. Rosenau said, that under laboratory conditions a temperature of 140 degrees Fahrenheit for 30 minutes is sufficient to kill the pathogenic organism found in milk. The whole question depends on whether or not the organism contained in the milk is heated to the required temperature for the designated period of time. No indications to date have been found that give any cause for requirements other than 145 degrees Fahrenheit for 30 minutes. This appears to furnish a reasonable margin of safety. The value of this study appears to lie in the careful valuation of various types of machines and the determination of the exact reliance can be placed on the time and temperature readings as indicative of the conditions to which the contained bacteria have been subjected.

### Laboratory Section

The most important papers presented before the laboratory section, Dr. B. L. Arms of Jacksonville, chairman, were a report by the reference committee on standard methods for the examination of milk, Prof. Robert S. Breed of Geneva, N. Y., chairman, and a presentation by Dr. W.

H. Park and his associates of the important steps recently taken in the laboratories of the New York City Department of Health in the improvement of the toxin-antitoxin mixtures for diphtheria immunization. Both these papers will be discussed in the December issue of THE NATION'S HEALTH. Other papers dealt with the bacteriostatic action of certain dyes on pneumococci and streptococci, with serum lysins, with standardization of cell suspensions, with certain puzzling problems of typhoid agglutination, with laboratory tests for syphilis, with the viability of colon bacilli in water, and the need for standardizing the position and qualifications of the laboratory technician.

### Vital Statistics

The section on Vital Statistics opened with a plea by Dr. W. H. Frost for the careful and scholarly study of epidemiological data by health department officials since the health department alone has at its disposal all the data necessary for studies of this kind. Dr. Haven Emerson defined epidemiology as "the study of diseases as they occur in groups" and cited the determination and the creation of specific immunity, the detection of carriers, the abandonment of gaseous fumigation, the shortening of isolation periods, and the campaigns against insect hosts as practical applications of advancing knowledge in epidemiology. Dr. E. C. Levy described some particularly helpful practical devices in use in Richmond for obtaining and analyzing epidemiological data. E. S. McPhail, at a later session, gave a historical account of the development of statistical procedures in Canada which gradually have achieved their present status of fair completeness and sound scientific value. F. L. Hoffman discussed the mortality statistics of South American countries, pointing out that there, as with us, the respiratory diseases and the diseases of infancy are of supreme importance. O. R. Eichel emphasized the need for improved birth registration and particularly for better data in regard to still-births. Prof. Raymond Pearl urged the need for caution in statistical evaluation of public health procedures; G. T. Palmer presented a plea for continued study of public health climatology under a central organization affiliated with the National Research Council.

Langdon Pearse, sanitary engineer of the Sanitary District of Chicago, gave a progress report of the special

committee on sludge disposal at the first session of the section on sanitary engineering. The report dealt largely with a statistical summary of the means of disposal in use in cities of over 25,000 population. In the discussion that followed the presentation of the report. Mr. T. C. Hatton of Milwaukee told of some interesting experiments that had been carried on with the cooperation of the State Department of Agriculture and with the advice of the Federal Department. Growing tests of various crops in various kinds of soils were carried on, using sludge and other fertilizing material. The detailed results are not yet available but visual examination of the crops while in the field showed practically no difference in the effect of the fertilizers used. Those in charge of the experiment feel that the greatest possibility for the use of activated sludge is in fertilizing lawn grass in the city park systems.

### Sanitary Engineering

At a later session Mr. Pearce presented a paper on "Typhoid Fever and the Water Supply and Sewage Conditions around the Great Lakes." A great variation in typhoid death rates is found in the cities of the Great Lakes Basin, one small city in Michigan having a rate of 98 per hundred thousand. There are few sewage plants around the lakes but considerably more water purification plants. Of these Toronto is the only one of any size that has a slow sand filter. The use of cross connections and dual water supplies in many of the steel mills of the Calumet region creates an interesting problem from the fact that sewage is so rarely treated in this locality.

George W. Fuller described the controversy which has arisen at Lima, Ohio, in regard to the Landreth "direct oxidation" process of sewage treatment, a subject discussed more fully in our editorial column. M. Z. Bair urged the importance of broadly conceived *mosquito* control rather than malaria control, and reference was made in the discussion to the fact that one hundred thousand cases of dengue fever have occurred in Florida during the past year. George W. Simons, Jr. discussed the methods employed in sterilizing suits and towels at public bathing places, and a paper by D. D. Kimball presented an abstract of the forthcoming report of the N. Y. State Commission on Ventilation which will be more fully treated in our December issue.

The proceedings of the Industrial

Hygiene section are reviewed elsewhere in this issue.

The remarks of the chairman, R. E. Doolittle, had to do with certain defects in the law which make supervision inadequate in the manufacture, sale, and labelling of drug products and medical preparations, a serious defect, since on the purity, strength, and potency of medicines, the success of treatment must depend, not to mention the protection necessary against fraudulent preparations and exaggerated claims. Local enforcement of minimum standards fails because of lack of personnel or funds and the Federal law has no jurisdiction on products made and sold within the confines of a single state.

### Glandular Therapy

Dr. Louis Klein gave a conservative and very thoughtful presentation of the thesis upon which glandular therapy is based—that of a specific hormone and the possibility of preserving this characteristic reaction in the pharmaceutical preparation. In most cases this expectation is not justified. Certainly exaggerated claims are current in this field, particularly in poster advertising which leads to the indiscriminate sale and self-administration of glandular products to a degree that properly constitutes a public health problem.

Lay inquiry has been immensely stimulated by the fact that some of the most spectacular achievements in medicine have been made in this field. It is a sorry fact that the indiscriminate use of these products is not confined to the laity. Hence the need of educating even the professional in the very definite limits of its application. The most recent achievement in the field, according to Dr. Klein, is the possibility that a specific for diabetes has been discovered by Drs. Bunting and West, in Toronto. This product has met all laboratory tests but is not yet on the market.

J. M. Doran discussed the dangers to the public health from "moonshine" whiskeys containing aldehydes and other toxic products.

Prof. H. H. Mitchell of the University of Illinois presented an admirable review of current knowledge in regard to the place of proteins in the diet, the difference in their digestibility and in their utilization within the body. He favored a fairly free use of protein foods except in hot weather. A report of Prof. H. C. Sherman of Columbia furnished an equally valuable summary of the present status of our knowledge in regard to vitamins.

In the section on Child Hygiene Dr. Florence L. McKay outlined the admirable New York State program for maternity and infant welfare. The policy of the state is against subsidies for local work but the state has organized a staff of regional consultants on obstetrics who give lectures at medical meetings, has created special machinery for training public health nurses in maternity and infant work, is prepared to conduct local surveys, and to furnish temporary pre-natal consultation and nursing service. Dr. H. J. Gerstenberger discussed the theoretical problems of infant feeding and described the excellent results obtained by the use of dried modified milk prepared on a large scale. Prof. A. L. Gesell urged the importance of adding a mental hygiene service to the children's dispensary, since in the pre-school period the main mental structure of the child is accomplished. Sensory-motor defectives and conduct defectives, as well as intelligence defectives should be detected and treated at this time.

Dr. Julius Levy cited figures obtained for five to ten cities and in more detail by counties in New Jersey which indicate that high mortality cannot be attributed to the service of midwives. Even in primiparas, and after eliminating abortions and miscarriages, the doctors and hospitals are charged with more deaths than the midwives. Partial explanation of the more favorable rate for midwives Levy found in the fact that they serve racial stocks that are sturdier and less susceptible to infection. Dr. Dunham urged the separation from the great group of malnourished children of the undernourished child previously exposed to tuberculosis, and the recognition of a distinct entity "potentially tuberculous" for consistent preventive treatment.

Particularly active interest was aroused by Dr. M. E. Champion's warning against the extension of child hygiene work in ways that may inhibit local initiative, antagonize the medical profession, or pauperize the individual. The fear which he expressed that clinic and nursing services under public auspices are tending to overstep an absolutely sharp line which he holds should be drawn between preventive and curative medicine, a view very generally held in Massachusetts at the present time, was vigorously combated by C. J. Hastings, L. I. Dublin, and others, Dr. Dublin pointing out that we do not pauperize a community by giving it a pure water supply or by com-

elling vaccination and that making people well is the antithesis of pauperism. Dr. Champion's emphasis on the advantage of beginning public health nursing before clinics are established, and the importance of administering nutrition clinics so that they teach dietary habits and do not merely feed children at reduced rates, received more general support.

### Public Health Nursing

For the first time public health nursing has had a Provisional Section of its own at the American Public Health Association meeting, and under the chairmanship of Miss Elizabeth Fox, the debut was a most promising one. Miss Margaret R. Burkhardt presented a summary of the chapter of the report of the Committee on Municipal Health Department Practise, dealing with Public Health nursing, indicating that the large cities of the United States have at present only about one-third of the necessary quota of fifty public health nurses per 100,000 population. Two types of nursing are at present most common, the specialized instructive service of the health department and the generalized service of private organization combining instruction with bedside care. The committee holds that a combined generalized service under municipal auspices, such as is found in half a dozen cities, is the ideal form of organization and that whether the nursing service of the health department be specialized or generalized it should be organized under a single administrative head who should herself be a nurse. Miss Elizabeth W. Holt described the encouraging progress made at Dayton along the line of the coordination of public and private agencies in a generalized service; and Miss Mary Laird emphasized the importance of follow-up work in the home.

### Health Education and Publicity

A second provisional section on health education and publicity opened its sessions with a "Clinic on Printed Matter," a critical examination of sample leaflets, circulars, and booklets submitted by various health agencies for the purpose. It was pointed out that much material of this kind failed because it is neither first class educational matter nor frank advertising matter. Getting anything across with the public depends on a simple, direct, and pulling statement of the subject, made with the realization that the attention must be caught instantly and that all must be said; that it cannot be as-

sumed that the person addressed has any advance knowledge of the subject. The importance of a concise journalistic "lead" in the opening paragraph is not generally appreciated by the compilers of these pamphlets, and particularly in the matter of titles, the main point of the argument should be featured.

Technical criticism on text matter was offered by a Cleveland business man, William Feather, and on art and general mechanical make-up by Henry Turner Bailey, Director of the Cleveland School of Art. Mr. Feather criticised many of the exhibited pamphlets as to methods of statement and particularly overstatement with consequent crowding of text pages. Mr. Bailey urged the wisdom of referring technical matters to technical men.

The moving picture was generally conceded to be the most popular and most effective means of health education, its limitation being marked by a dearth of suitable subjects and

weak execution. Mr. Clark of the National Health Council reported progress toward getting talented workers in this field and toward centralizing the production of health films. Dr. Kleinschmidt exhibited excellent models and cues for health education based on objective methods. It was emphasized in the discussion that health films will be better when they become commercially profitable. At least one firm is on the look-out for real scenarios on health subjects and at least one ambitious health film has been written commercially of late.

At the closing session of this section the problems of newspaper publicity were discussed by Marjorie Delavan of the Michigan State Department of Health, Charles Freiburger of the Detroit Department, Dr. J. N. Hurty of Indiana, Erie C. Hopwood, editor of the Cleveland Plain Dealer, and Dr. W. A. Evans of Chicago. Such critical analyses by health promoters of their own methods is a most hopeful sign of the times.

## Social Hygiene Conference

THE American Social Hygiene Association held its annual conference at Hotel Statler, Cleveland, immediately following the meeting of the American Public Health

Dr. William F. Snow, general director of the American Social Hygiene Association. Dr. Snow received the degrees of A.B., A.M., and M.D. from Stanford University. He is treasurer of the National Health Council and chairman of the Common Service committee. During the war he was a lieutenant colonel in the Medical Corps in charge of Venereal Disease Control.

Association, October 19, 20, and, as usual, attracted a widely representative gathering from all parts of the country.

Dr. W. F. Snow introduced Dr. Ed-

ward L. Keyes, Jr. as chairman of the opening session and, after a tribute to Prince Morrow as the father of the organized social hygiene movement, Dr. Keyes reviewed the triumphs of the "American idea" in the control of venereal disease in military life during the war. Dr. Haven Emerson reviewed the progress which has been made in Cleveland in carrying out the program indicated by the health survey of three years ago and pointed out that in the development of machinery for dealing with tuberculosis and venereal disease hoped for advances had not been made.

The growth of the liberal attitude on the part of the medical profession was most encouragingly illustrated, however, by a recent resolution of the public health committee of the Cleveland Academy of Medicine endorsing the free clinic treatment of patients in a contagious stage of venereal disease without regard to economic considerations. The importance of supplementing such negative measures directed against venereal disease by positive measures contributing to healthy sex relations in the widest sense was a key-note of the meeting particularly emphasized by Dr. Benjamin C. Gruenberg whose book on "High Schools and Sex Education," recently published by the United States Public Health Service, constitutes perhaps the most important

contribution yet made to the complex problem of sex education.

A later session dealt with protective social measures. Participating were Mrs. D. S. Bachman of the Ohio League of Women Voters, Miss Sabina Marshall and Mrs. E. R. Wembridge of the Women's Protective Association, Dr. Valeria H. Parker of the Woman's Christian Temperance Union, and Mrs. Ann Webster of the National League of Women Voters. The importance of the problems of mental hygiene and the need for standardizing and improving machinery and personnel in protective work were emphasized by most of the speakers. The National League of Women Voters has placed to the fore of its program the task of obtaining legislation for continuing the work of the Inter-Departmental Hygiene Board; and during the present intermission of this work Dr. Parker and Mrs. Falconer, acting jointly for the American Social Hygiene Association and the Department of Social Morality of the W. C. T. U., are prepared to furnish counsel in regard to procedures and personnel. The demand for trained policewomen and clinic workers, according to Dr. Parker, greatly exceeds the supply. Dr. Parker gave the welcome news that the last segregated district officially recognized in any large city, at Reno, Nev., will be closed November 1.

A peculiarly significant feature of the meeting was the paper by Dr. Katherine B. Davis of the Bureau of Social Hygiene of New York on "Unsettled Questions in the Social Hygiene Field." Dr. Davis pointed out that many of our most fundamental problems are unsolved. We do not know what constitutes a normal sex life in the broadest sense. There are some who even doubt whether the compatibility of continence with thoroughly normal mental life may be considered certain. The Bureau of Social Hygiene was established for research in this complex field. It is at present analyzing the results of a confidential questionnaire returned by over one thousand married women in regard to their sex life which promises to yield results of the highest value and a similar questionnaire will shortly be sent out to unmarried women. The establishment of a National Committee on sex research under the National Research Council will greatly aid in stabilizing investigations along such lines.

Under the somewhat unappetizing title of an "educational luncheon," R. E. Lewis of the Cleveland Y. M. C. A.

presided over a discussion of the work of the Cincinnati Social Hygiene Society by E. F. Van Buskirk and a discussion of the Community Plan by Dr. M. J. Exner of the American Social Hygiene Association, and P. B. Williams of the Community Committee of Toledo.

The work in Cincinnati includes the education of mothers by lectures to mother's clubs, the circulation of loan libraries, lectures to Parent-Teachers Associations, the stimulation in many ways of sex education in the common schools and normal schools; the education of the general public by talks to Y. M. C. A., Rotary Club, church, boy and girl scouts, and industrial groups and by the circulation of literature.

### Is Community Problem

Dr. Exner emphasized the fact that Social Hygiene is a community problem not to be solved by any specialized group. After a conference of representative community leaders, a community committee should be organized to coordinate a systematic plan for educating the adults of the community. In discussion the need for frank treatment of sex problems in school texts on physiology and the importance of recreational facilities were emphasized.

The final session, under the chairmanship of Dr. William Keller of the Cincinnati Social Hygiene Association, was devoted to a consideration of the work of voluntary and official agencies. The functions of the voluntary agencies were discussed by B. C. Roloff of Illinois, who pleaded for a flexible program adapted to local conditions and personalities, the surveying of treatment facilities; educational work in industry and with the Knights of Columbus being among the important tasks in Chicago; and by Dr. Rachelle Yarros of the General Federation of Women's Clubs who brought an inspiring report of the progress of social hygiene in England and France. Dr. J. S. Lawrence of the New York State Department of Health and Dr. J. G. Royce of the Indiana Department of Health outlined the rôle of the state. Dr. W. F. Snow summed up the significance of the meeting in its relation to the general program of the American Social Hygiene Association.

Many health films were shown during the conference. The new dramatization of the fall of the death rate under pressure of science and administration, the Health Twins at Work, being received with the most cordial appreciation.

## The Detection of Spoiled Canned Food

Suggestions to dealers and consumers in the purchase of canned goods are set forth by Dr. Charles Thom, Bureau of Chemistry, U. S. Department of Agriculture, in the *Cincinnati Sanitary Bulletin*. The dealer is advised (1) to inspect every container when the case is opened; (2) not to accept or sell any can which shows a "swell," "springer," "flipper" or "leaker;" in glass, to examine the cover and the seam and inspect the contents for sign of spoilage; (3) to reject the lot if it shows many swells; not to take the responsibility of sorting a bad lot of cans; (4) to demand a well-exhausted pack, every can showing good vacuum with clean and bright metal.

The consumer should in buying reject any can in which both ends are not flat or do not curve slightly inwards; in which the end bulges, snaps back when pressed, or feels loose. In glass, the consumer should see that the cover is firm, flat or concave, with seam, collar band and label, clean and free from all signs of leak. The contents should appear free from mold, disintegration, cloudiness or other abnormality and should show no discoloration.

If the following conditions are noted by the consumer when the can is opened a maximum of safety will be obtained: (1) suction inward; (2) no outrush of gas or spurt of liquid; (3) the odor should be characteristic of the product; (4) no trace of foreign or objectionable odor; (5) no disintegration, no mold or other abnormal appearance; (6) liquor enough to cover the food in most products; (7) the inside of the can should be clean and bright, or well lacquered, not extensively blackened or markedly corroded. If the food is spoiled, it should be destroyed. If after examination there is still doubt as to its condition, add half the volume of boiling water and boil thoroughly.

The Simmons College Catalog announcing courses for 1922-1923 includes a new two year pre-medical program which is arranged to meet the admission requirements of medical schools of the Class "A" rating adopted by the American Medical Association. This announcement will interest many women who are planning to go into medicine as a profession as the required arrangement of courses is not ordinarily possible in women's colleges.

# Hygienic Measures of the Southern Pacific

## Cleanliness and Rigid Inspection Protect the Patron of these Lines

By J. H. DYER, GENERAL MANAGER, SOUTHERN PACIFIC COMPANY, (PACIFIC SYSTEM), SAN FRANCISCO, CALIF.

**S**OUTHERN Pacific Company has always been a leader in efforts to increase the safety of the traveling public, and these efforts, crowned by the winning of the E. H. Harriman Memorial Medal in 1914, under conditions submitted by the American Museum of Safety, naturally include complete sanitary and hygienic measures to safeguard the health of the company's patrons. The United States Sanitary Code governs the carriers as to sanitary and hygienic measures but the Southern Pacific observes the spirit as well as the letter of the law and constantly seeks to improve its work along these lines, suggestions promoting this result being received with the same eagerness as suggestions for increasing safety, improving service, or operating methods.

In following out the definite regulations of the government, both federal and state, Southern Pacific employees have their own rule of thumb guide—"keep things clean"—to assist them. It is this spirit which finds expression in the appearance of the right of way, buildings, grounds, and equipment. Section foremen are as jealous of the appearance of their sections as a housewife of the spotless condition of her kitchen.

The care taken by the Southern Pacific Company in sanitary and hygienic measures, matters involving countless details and extending into all branches of the service, is well demonstrated by the provisions for supplying pure drinking water to patrons. In handling drinking water in the company's passenger equipment, the greatest care is taken to keep the water clean and uncontaminated. It was formerly the practice to extend the water tanks through the roof of the car, the ice and water being placed in one receptacle from the roof. To obviate any danger of dirt from the roof obtaining access to the tanks, and of the drinking water becoming contaminated with impurities from the ice, the Southern Pacific Company has improved the water containers to eliminate these possibilities. Tanks are now used which have a separate compartment for the ice, so that it does not come

in contact with the water. Automatic drinking fountains of the bubbling type have been installed at all important stations and on ferry steamers. The water in these fountains passes through coils of pipe which are thoroughly iced.

Employees who ice and water the cars, in addition to being thoroughly supervised in matters of cleanliness, are required to wear white duck uniforms and caps, and white rubber gloves while performing these duties. These uniforms are laundered and kept serviceable at the expense of the company. The men are required to change them frequently and to present a neat appearance at all times.

The ice, while being transported to cars in carts, is kept covered with clean white canvas. These carts, and water and ice tanks, are steam cleaned and sterilized at frequent intervals. Terminal yards are provided with steam tables having pipes which discharge live steam upwards. In sterilizing the containers they are inverted over the pipes and the live steam turned on. Each cooler is sterilized every week and a record is kept in the car of the last date of

cleaning and steaming. All water and ice used for drinking purposes at stations and on trains operated by the Southern Pacific Company are examined by the health authorities and a certificate is furnished the company at regular intervals indicating that they are entirely satisfactory for drinking purposes. Most of the ice used is made from distilled water.

Passenger trains and stations in the arid districts are supplied with water, carefully conveyed in thoroughly sterilized twenty-gallon cans, from artesian wells. The water from these wells is known for its purity and refreshing qualities.

Advance steps have been taken in industrial hygiene and sanitation by the Southern Pacific in its commissary department. A rigorous procedure is followed to keep the cars spotlessly clean, to keep the food fresh in its original state, and to obtain only the best supplies from the most reputable sources.

Before going out on a run, the dining car, like other cars, is given a thorough cleaning by the car cleaners, every particle of dust being removed, the windows polished, and the

In order to insure that the drinking water is uncontaminated, the water containers are sterilized with live steam. The ice is kept in a separate compartment and does not come in contact with the water.

Men engaged in the work of icing cars wear white duck uniforms and gloves. The ice carts are sterilized with live steam frequently and the ice is kept covered with clean white canvas.

walls rubbed down. At the end of each run all utensils are taken from the car to the main commissary and there placed in large steam chests and live steam turned on until they are thoroughly sterilized.

The dining cars and restaurants are closely watched by the department's inspectors. The dining car crews expect to be closely watched and are always prepared. Crews remain intact for long periods and the inspection is something of a game between the crews and the inspectors, as any old soldier who is careful to keep the heels and backs of his shoes well polished and all his pockets buttoned will understand. The cars are always inspected on leaving a terminal and on arrival at destinations, and usually at least once or twice en route.

There are tricks of the trade in this inspection. The inspector can look at the inside of the metal caps of the salt shakers and never find any verdegriis; he can unscrew the caps from the ketchup bottles, or look into the spouts of the coffee pots and find them clean and shining; he can rub his finger along the shelves of the chill boxes, top or bottom, and always find them spotless. The table tops and drainboards are scrubbed white. It is these little indications that show the importance attached to cleanliness in dining car operation.

The commissary department men through years of experience have learned the best methods for keeping

perishable commodities in first class condition. An instance of care in this regard is the packing of fish. Fish is not carried in a chill box, but a heavy packing of ice, first being wrapped in freshly laundered linen so that it does not come in contact with the ice itself.

It is a strict rule that all linen must be spotless. On a three-day run a dining car is stocked with over 2,000 pieces of linen, including 220 tablecloths, 1,000 napkins and 250

doilies, besides waiters' coats and aprons. The waiters' coats are laundered free of charge at the company's laundry at Oakland, Calif. As a sanitary measure, the napkins as they come from the iron are folded and placed in paper cartons so that they come straight from the laundry to the passenger untouched.

The care used in obtaining food supplies is shown in the efforts made to secure the best milk and cream. Milk and cream used by the company are tested each week by M. E. Jaffa, Professor of Nutrition of the University of California. The butter fat content is higher than the standard required by the various states. The department thoroughly investigates the sources of milk supply before making contracts, and the milk and cream comes from the finest dairy herds in the West. One of the herds supplying the company's dining cars is composed of registered Guernsey stock, many of the animals having been imported from abroad. The milk is bottled and sealed at the dairies and is not uncapped until placed on the tables. Cream is received in one gallon air tight cans which are non-refillable, and which are sterilized at the dairies before initial filling.

All garbage and refuse are kept in covered containers in a low temperature refrigerator box built especially for the purpose. The elimination of flies receives the most careful attention.

In the commissaries there are ample cold storage accommodations and

Carpets, rugs, aisle strips, mats, cushions, hassocks, and mattresses are cleaned either with compressed air or by vacuum system.

An attachment to the locomotive tender used in sprinkling the roadbed with water keeps down the dust. Many miles of roadbed are oiled for the same purpose and the locomotives of this line burn oil thus eliminating in great measure dust and cinders.

all supplies are kept under refrigeration.

The Southern Pacific Company operates a school for cooks and waiters, and sanitary measures and the careful handling of food are emphasized in the course of instruction. Cooks and waiters are required to pass rigid physical examinations.

When bread is received from the bakers it is wrapped in a paraffin envelope. A special make of butter is contracted for. It is double wrapped in paraffin paper and placed in heavy cardboard cartons. It is cut by a machine and from the creamery to the table is never touched by hand.

All cars used in the transportation of passengers are thoroughly renovated and cleaned at the end of each trip and are fumigated at frequent intervals. Carpets, rugs, aisle strips, mats, cushions, hassocks, and mattresses are cleaned with either compressed air or vacuum system. Every effort is made to keep the cars in a clean and healthful condition.

Disinfectants (carbolic acid and formaldehyd) are placed in all water used for mopping floors, cleaning around heater pipes, or seats. Cars are frequently swept out at stations enroute by men employed for that purpose in addition to work done by the porters during the journey.

The state boards of health of the various states served by Southern Pacific Lines cooperate with the company in the matter of train inspection, both as to sanitation and clean-

liness, with a view to insuring greater protection and comfort to passengers. These boards report to the medical department of the company, which thereupon takes prompt action.

In the company's ferry service on San Francisco Bay, the same precautions are taken. Light cleaning is carried on all during the day and night during the runs, and after the boats are tied up for the night, the heavy cleaning commences. The main deck is then washed down with a large hose, lye and sand, the outside of the boat is washed down, all windows are cleaned, toilets scrubbed out with lye and water, with disinfectant added to the water, cuspidors given a thorough cleaning and sufficient disinfectant put in each cuspidor. During the day when the main deck is sprinkled, a sufficient amount of disinfectant is added to the water. The steamers are frequently fumigated. Toilets are cleaned, the paintwork scrubbed, and the bowls and urinals washed after every heavy trip. Steamers and large stations are provided with matrons and porters to look after the cleanliness of lavatories and to assist aged, infirm or sick passengers.

The California State Board of Health in its monthly Bulletin of August, 1921, ran an article under the heading "How the Southern Pacific Maintains the World's Cleanest Ferry Boats," showing in detail how the company keeps its vessels in a sanitary condition.

The Southern Pacific Company annually oils hundreds of miles of roadbed to prevent dust, particularly on its roadbed in arid regions, and to some extent where material composing the ballast is light or fine, or where it carries considerable dirt. A special oil sprinkling device is used for this purpose. A water sprinkling device has just been designed by a Southern Pacific official, and this is being used over several arid sections. Southern Pacific locomotives burn oil, thus eliminating coal dust and cinders.

### Bacteriology of Dry-Cleaning Processes

The dry cleaning process, a stern necessity in the cities, and more and more relied upon for the rejuvenation of fabrics, has not until recently been investigated from the angle of its bactericidal effects; but during the early part of 1921 eleven of the most progressive firms of cleaners and dyers in the United States organized themselves for the purposes of research and endowed an industrial fellowship in the Mellon Institute of Industrial Research of the University of Pittsburgh, where technical investigation of processes was carried out.

A report just issued of an investigation into the bactericidal efficiency of the dry-cleaning process shows that as many as 90.1 per cent of the most hardy and resistant bacteria and 99.99 per cent of the less resistant bacteria were killed in the cleaning process. The destruction of organisms used in these tests, such as the very hardy hay bacillus (*B. subtilis*), which is widely distributed in air, water, and earth, indicates that pathogenic bacteria, such as the organisms causing tuberculosis, diphtheria or typhoid fever, would undoubtedly be destroyed.

In one of these tests the bacterial count was 2,700,000 per square inch of cloth before being dry-cleaned, and after the cleansing process the count was only two hundred per square inch. In another experiment the bacterial count was 1,200,000 per square inch, and the dry-cleaning process reduced the count to only five hundred.

Under average conditions the dry cleaning processes investigated would practically free a garment from bacteria. Many so-called cleaning establishments employing only the most superior methods, and established without adequate facilities, in cellars or back rooms, need to be inspected and rated according to their sanitary efficiency.

# Community Movement and Health Activities

## Great Potential Value to Health Work in Community Pride and Action

BY IAGO GALDSTON, M.D., INDUSTRIAL SECRETARY, NEW YORK TUBERCULOSIS ASSOCIATION, NEW YORK CITY.

THE community council movement, some two years ago, at the height of its development promised to prove one of the best and most effective allies of community health activities. This article is written in an endeavor to demonstrate that it is in the interest of all social agencies aiming at the spread of health education to cooperate with those interested in, and to assist and stimulate the development of, community consciousness and organization.

To appreciate the significance of the community movement one needs first to survey our large metropolitan cities and to notice what extremely complicated and unwieldy organizations they are. When one considers New York, Chicago, Detroit, or any of the smaller cities, east or west of the Mississippi, one realizes that each is extremely heterogeneous in composition and complicated beyond unravelment in the various cross-currents of interests and customs that spring from the different groups of peoples that make up the population of each.

As organized at present, this heterogeneous mass of humanity has hardly any means for the intelligent expression of its total or individual interest, of its desires, or even of that *esprit de corps* that must of necessity spontaneously emanate from any group of convivial individuals. Save for the extremely unsatisfactory annual political expression along the relatively meaningless party lines, there is no provision for the individual in the community to express his opinion on, or to participate in, community function. Centralized administration gives little more than an unsatisfactory average result, and the individuality of the citizen is lost in the characterless composite of the average.

This is a microscopic view of the large cities. When, however, one makes a more searching study, one discovers that there is an inherent and spontaneous process of crystallization constantly going on within the community. Like elements seem to cohere, to congregate in certain sections, to participate in common in economic and social functions, and thereby to cast faint outlines of a

community organization. The large mass which represents the city, when closely examined proves to be split into many small segments each representative of a small community. These segments are found to be organized around such common poles as race, religion, economic status, and political thought. This process of community crystallization upon examination is found to lack that definiteness and purposiveness which can come only with intelligent direction, and the communities so organized spring rather out of inherent necessity than out of conscious endeavor. Because of this, these community organizations are imperfect, exploit only the primitive instincts of the masses, and are essentially clannish in their spirit.

These groups are the basis for our future community organization. In a large measure, all that is necessary, in order to render these community organizations intelligent and motivated by the highest social interests, is for a group of individuals, who themselves appreciate the value of community organization, to act as the precipitating agents and to give early thought and voice to the community. In this way "man takes his fate out of the hands of destiny" and places his own intelligence and energy back of the blind and forceful efforts of social nature. The community when organized along well thought out plans, and on the basis of a clearly defined program allows for the development of the special character of each community and the harmonization of the same with the characters of the other communities. The clannish spirit can be overcome, and various communities can be brought in contact with one another through a central representative body, and through a series of oft repeated, wide community celebrations. Incidentally this process of community contact would prove an extremely effective means for the true Americanization of our foreign citizens; for that manner of Americanization which aims at the development of the American spirit without the loss of whatever is beautiful, cultural, and precious in the new citizen's native thought and custom.

In every community organized along the lines defined, it would prove a relatively easy task to impress upon its members their own responsibility in the matter of community health, and to instruct them in the ways in which they can discharge their individual and community obligations. In each case there would be a community pride as a basis for appeal and interest, and there would be a community machinery through which to put into execution whatever plans might be formulated for the improvement of individual and community health. Communities could be induced to compete among themselves for the improvement of health conditions. Community organizations ready to cope with any arising emergency could be developed and kept ready for service.

Cities, as organized today, are too clumsy for a ready manipulation in time of social emergency. But where a community is organized and the citizens of the community know their own resources, their hospitals, their clinics, their community physicians, their public schools, and their health centers, when an emergency appears no time needs to be lost nor efforts wasted in putting the community means at command to the best of uses. In the last great influenza and pneumonia epidemic, though the community organization in New York City was small, much effective work was done in securing medical and nursing help in the districts of the community councils. These councils, at their own expense, printed placards giving names, address and telephone numbers of central points in each community at which information could be secured relative to medical and nursing help. Arrangements were made at these centers for helping needy cases. Coal, food, and drugs were provided for those who were in need and in many other ways much was done to render the acuteness of the situation less sharp. Despite, however, the effective services rendered by the Community Councils the movement has suffered collapse and what remains bears inadequate witness to the movement's former size and momentum.

In seeking to account for the proc-

ess of disintegration suffered by the movement, many factors may be brought to mind. Chief among the causes stand out the following: (1) There were relatively few persons in executive positions in the individual community councils sufficiently well trained and having complete and thorough enough a concept of the basic aims of community movement, and of the most competent forms of organization through which such aims might be attained, to render possible a consistent development of the established councils. (2) The community movement, because of the war and its accompanying intensity of feeling and sentiment, suffered a mushroom growth, which at the end of the war, due to the complicated political situation arising out of the coming of peace, collapsed like a punctured balloon. But over and above these causes, perhaps, comes the fact, (3) that after having gone through the more or less interesting processes of organization, those in executive positions in the local community organizations *did not know what to do, or how to do it.*

The writer can remember one meeting in which certain of the leaders of our health work participated, and which was called with the specific aim of considering what Community Councils could do along the lines of health conservation. The organization was there, but was suffering physical and spiritual atrophy due to lack of function. Nothing came out of that meeting and yet, perhaps, had the health organizations then represented taken a more active interest in the community council movement, had they taxed its resources in the execution of some definite plan of health work that would have at the same time put into play the specific machinery of the various health organizations and the large masses of citizenry included in the councils, both the councils and the health organizations would today be much the better off for the efforts, and the major portion of the energy invested in the councils would not have gone to waste.

The very evident deduction prompted by all the foregoing is that we have in most of our cities the basis for a real and vigorous community movement and that the community movement is necessary for the bringing to the surface and into operation all that is valuable and precious in the various groups that make up our cities. Most health work, and especially that part which deals with health education, can best and most effectively be carried on along the lines of the community. And from

all this it follows that it were wise for the various health agencies to stimulate and promote the community organizations in cooperation with those more especially interested in the development of the community councils. Profit would accrue to all concerned, and most of all to the community itself.

At first it may seem as if the health organizations, in the execution of this plan, would need to go far afield, but upon closer examination it will be seen that this is more a matter of appearance than of reality. It would take but little additional effort on the part of a health center to draw about itself and incorporate into its own functions the other activities of the community. In fact, the effective services of the health center would undoubtedly be increased many fold when associating with the other leading agencies of the community. It takes a relatively small group, and but little effort on the part of this group, to organize the community. The

health center, the leading churches and synagogues, the county or district medical society, the principals and teachers of the community's schools, the leading business men, real estate owners, parent associations, etc., all of these coming together and working along the lines of their community interests can quickly develop a competent group of community leaders, whose united efforts cannot but result in developing a deep social consciousness in the community. The community organization formed, the various health agencies can then exploit its machinery in the interest of better health and longer life.

This scheme deals exclusively with the residential community, but its major truths are equally valid for the industrial community. Here the methods of organization may differ slightly but again the necessity for community work is as deep as elsewhere and the agencies of health may again play leading and prominent parts in the processes of community organization.

## Detroit's School Health Plan

**D**ETROIT has introduced an innovation in school medical inspection. It has removed this service from the hands of part-time physicians in the employ of the school board and placed it under the supervision of the city department of health.

The new Detroit plan insures thorough physical supervision for all its school children. The teachers make the preliminary examinations of the pupils, school medical inspectors checking only those referred to them. Under this system vaccination and diphtheria immunization are in the hands of four specialists; disease diagnosis is in charge of eight men assigned to districts. Suspicious cases of disease are referred by nurses to the main office, and thence they are given out to the proper district physician. Examinations of physical defects are carried out by twelve men who work in teams of three, each team being assigned to a district. Diagnosticians fit their work in with their private work, and vaccinators and physical examiners give half time, from 8:30 to 11:30 each day.

In order to make the examinations uniform, a graded scale is used in marking defects. Each physician is assigned a list of defects to look for. One observes mouth breathing, tonsils, teeth, palate, cervical glands and thyroid, another tests vision and hear-

ing, and a third observes heart, lungs, skin, anemia, orthopedic defects, and phimosi. As the children pass by, the physicians call off their findings in terms of the scale and the nurse or teacher makes entries on the children's cards. These details are forwarded to the central office, recommendation slips are made out to the parents, and the school nurse makes a record of all defects to be followed. Of 4,056 underweight children examined in 80 schools, 47 per cent showed either enlarged or infected tonsils; 19 per cent had defective teeth.

Subsequent examination by physicians of the 2,500 children examined by school teachers showed that as a rule the teacher reported more defects than the physician. If this plan is perfected, it would be the policy to have all children examined by the teachers at the opening of school. Medical teams would then inspect only those children designated for attention and recommendation slips for treatment would be sent to the parents. It is maintained that the teachers are capable of grading thyroid, vision, hearing, mouth-breathing, tonsils, skin, anemia, teeth, palate, cervical glands and orthopedic defects, though they cannot examine for lung and heart affections.

"The system is a marked step forward in this field of public health," states George T. Palmer, epidemiolo-

gist, Detroit Department of Health in the *American Journal of Public Health*. "Teachers would become intimately acquainted with the physical capabilities of their charges as well

as with their mental capacities. The extension of this work would include the introduction of courses in physical examination into the normal and teachers' training schools."

the American Army Medical Corps, who conducted a series of experiments, the most significant of which were upon groups of Bilibid prisoners. In the three groups of these prisoners classified by the nature of their former occupations, the lowest percentage of hookworm infection was 54 and the highest 100.

It is expected that the stamping out of the hookworm infection will so improve the general physical condition of Filipinos that the number of malaria and tuberculosis cases will be materially lessened and the vitality and stamina of the race improved.

## The League Health Committee

THE fourth session of the Health Committee of the League of Nations, the last to be held before the third Assembly, met in Geneva from August 14 to 21. A review of some of the more important matters considered at the recent session gives an indication of the past activities and the present position of this provisional health organization at the close of its first year of existence.

Consideration was given to such matters as the arrangement with the Rockefeller Foundation, the interchange of sanitary personnel, the recommendations of the Warsaw Health Conference, the report of the epidemiological situation in the Far East, and reports on the work of the Health Organization since last May and of the Epidemic Commission during the last year. Arrangements have been practically concluded by which the International Health Board is to finance epidemiological investigations and intelligence for a period of five years and the interchange of sanitary staff for three years. Funds will be available for the former project to the extent of \$150,000 and for the latter \$180,000. Provisions were made for the first interchange of sanitary staff in October. One public health officer from Bulgaria, two from Czechoslovakia, two from Belgium, two from the Serb-Croat-Slovene State, five from Italy, five from Soviet Russia and the Ukraine, and five from Poland will be given a two weeks' course at Brussels followed by two months' observation of the working of various practical public health systems. This initial experiment in providing international experience in health work should reveal many fruitful possibilities.

The Health Organization was referred to as mediator in the sanitary conventions being concluded between the states of East and Central Europe and was designated by the All European Warsaw Health Conference as the executor of the latter's plans for an anti-epidemic campaign in East Europe. The Health Organization, which has been steadily at work in Poland, has formulated plans for extending its activities northward into Latvia and eastward into Western

Russia and the Ukraine. The Committee has given strong support to these plans in a resolution to the Council urging the need of additional funds for this purpose since Russia is still ravaged by epidemics and great numbers of refugees and repatriated persons are still crossing the frontier into the border states.

A revised draft of Parts II, III, and IV of the International Sanitary Convention text has been prepared by a Mixed Commission of Inquiry sent by the Health Committee and the Office International d'Hygiène Publique to investigate the working of sanitary administration in the Near East.

The committee decided in principle upon sending a small commission of inquiry to the Far East to study the prevalence of plague and cholera in seaports and practical means of preventing their transmission. Approval was also given to the appointment of three experts for a study of sleeping sickness and tuberculosis in equatorial Africa and to aid the Mandates Commission in drawing up questionnaires on these subjects.

In the furtherance of international organization, the Health Organization has absorbed the Epidemic Commission and established cooperation with the Office International d'Hygiène Publique, and is collaborating with the Opium Commissions, the League Mandates, and the International Labour Office.

The committee closed its session by deciding to coopt a German member and to meet again in plenary session on January 4, when it is hoped that Dr. Chaga (Brazilian) and Dr. Josephine Baker (American) can also be present.

An American official investigation has disclosed the fact that about 90 per cent of the inhabitants of the Philippines have the hookworm infection, with the result that an educational and preventive campaign will be instituted that is expected greatly to raise the vitality of the people of the islands.

The Official survey was conducted by Dr. Frank G. Haughwout, Dr. Leach of the International Health Board, and Major James E. Ash of

## The Little Enemies of Man Still Uncontrolled

It is only within the last few years that man has learned what his greatest enemies are, says *The Scientific Monthly*, and he has not yet found adequate weapons against them. Early in the history of the human race man learned how to conquer the mastodon, but he has yet to learn how to master the microbe. Whales and elephants are now almost extinct, but mice and flies still increase and multiply, and bacteria, the smallest and most dangerous of all, constantly find new ways of attacking us. The explorer in tropical jungles used to fear the lions, tigers and pythons; now he protects himself most carefully against the mosquitoes and tsetse. Mars has afflicted the human race less than Beelzebub.

Although we theoretically accept the conclusion of science that a man's foes are those of his own household, we are not yet aroused to the necessity of waging war in earnest against them. We have a secretary of navy and we give him millions for defense, but we have no secretary of sanitation, though that is a more necessary office. It is quite improbable that any American will be killed by an invading army this year, but our land is invaded by millions of mosquitoes and flies armed with deadly weapons and certain to slaughter thousands. Years of study and experimentation will be necessary before we learn how to fight our insect foes, but already enough has been done to show what can be accomplished if we go about it in the right way. Many of the sanitary measures of the past we now know to be crude, clumsy and misdirected, yet they are fixed in the popular mind and remain on our statute books. People still talk about the dangers of miasma and sewer gas, and think a deodorizer is a disinfectant.

A research fellowship of \$1,000 for the study of orthopedics in relation to hygiene and physical education has been offered by Wellesley College.

# Heart Disease as a Public Health Problem

BY CARY EGGLESTON, M.D., COMMITTEE ON EDUCATION, ASSOCIATION FOR THE PREVENTION AND RELIEF OF HEART DISEASE, NEW YORK CITY.

THE prevention and relief of heart disease constitutes one of the major public health problems of today because (1) heart disease is the greatest single cause of death; (2) heart disease is very largely preventable; (3) heart disease causes prolonged suffering and incapacity on the part of affected individuals; (4) adequate medical, social, and industrial guidance is capable of preventing this suffering and incapacity to a very great extent; and (5) the physical handicaps, the curtailment of industrial capacity, the prolonged and frequently recurring need for hospital care, as well as the enormous loss of life which are caused by heart disease place a tremendous economic burden upon the community which can be greatly reduced by appropriate coordinated measures for prevention and relief.

Heart disease causes more deaths than either tuberculosis or cancer, being responsible for nearly one-eighth of the total deaths at all ages in the whole registration area of the United States, and for approximately one-fifth of the deaths from all causes in persons forty years of age and over. Not less than two hundred thousand persons die annually in the United States from disease of the heart, which means that there is one death from this cause every three minutes of the twenty-four hours. Not only does it rank first among all the causes of death, but heart disease cuts in half the life-span of its victims, and it is to be remembered that heart disease is a disease of youth and early adult life.

## A Secondary Disease

Accurate statistics as to the frequency of occurrence of organic heart disease in the general population are not available, but a conservative estimate based upon the examination of different large groups of persons indicates that there are between two and four million people thus affected. Of the young men called in the draft 4 per cent were rejected for service because of heart disease, and 2 per cent of the applicants for

life insurance are refused for the same cause. Definite disease of the heart has been found in 2 per cent of industrial workers, and from 1½ to 2 per cent of the children of school age are found to have serious heart defects. Finally, it has been conservatively estimated by Dr. Haven Emerson that between 1 and 2 per cent of the community at large are at any time in need of care and medical attention because of heart disease.

Heart disease, as the term is commonly used and as it is here employed, is not an entity like typhoid fever or tuberculosis. It is seldom, if ever, primary but occurs as a sequel or complication of some other disease. It embraces all of the organic affections of the heart itself, of its blood vessels, and of its lining and surrounding membranes. However, since the diseases of these several structures have in common most of their causes, their symptoms, and their end results, it is wholly justifiable to consider them as an entity and to give them a common name.

## The Problem Is Diverse

The control of heart disease presents a number of diverse problems and demands the cooperation of physicians and health workers in many different fields, as well as the education of the public in methods of prevention and in the need for early diagnosis. To accomplish this it is necessary to have some form of central coordinating organization, which fortunately already exists in the Association for the Prevention and Relief of Heart Disease, New York City. This Organization, founded in New York City seven years ago, has led to the formation of similar associations in other large cities, and all of these are now uniting in the establishment of a national organization so that the machinery for proper coordination of work is already at hand in an active and effective form.

Herein is presented a brief review of the methods of preventing heart disease and of reducing its economic drain upon the individual and the community. The prevention of heart disease demands an accurate and comprehensive knowledge of its causes. While there are still some gaps in our knowledge, they are not sufficient to prevent an effective beginning from

being made while further comprehensive investigations of the many possible causes are being undertaken.<sup>1</sup> Rheumatism and syphilis are among the most frequent causes of heart disease, the former especially in early childhood and in youth, the latter in middle adult life. The less frequent causes of heart disease also include scarlet fever, diphtheria, typhoid fever, carious teeth, infected tonsils, and various cryptic foci of infection. Disease of the kidneys, senescence, the ill defined condition called arteriosclerosis, and toxic states such as that associated with thyroid disease occupy important but undetermined positions as causative factors.

## General Measures Important

Nowhere, perhaps, is the dictum that disease control rests upon the general elevation of the health of all better exemplified than in the prevention of heart disease since it embraces the control of each of the causative factors mentioned. Rheumatism, scarlet fever, diphtheria, and infected tonsils are characteristically diseases of childhood and early youth and are the evident underlying causes of the vast majority of cases of heart disease in persons below the age of forty. Examinations of school children show that heart disease increases gradually as the ages of the children increase so that it is nearly twice as frequent above fourteen years of age as it is at eight. So far as these diseases are concerned, therefore, the control of heart disease through their prevention or prompt alleviation must begin in the first decade of life. It is not possible to enter into the details of the various methods of prevention of these several causative diseases, but it should be pointed out that the maintenance of good general hygiene and proper and sufficient food are measures of great importance. Periodic examinations of the children and the prompt isolation of all individuals presenting even slight attacks of fever or colds are measures of the greatest prophylactic value.

Chronic foci of cryptic infection, chronic dental caries, and infected tonsils should be attended to promptly and evidence shows that rheumatic fever and heart disease can be diminished in children by the early removal of diseased tonsils and adenoids.

1. An extensive statistical study of the causes of heart disease is now being made by the Association for the Prevention and Relief of Heart Disease, 325 East 57th Street, New York City. Blank information charts will be provided to any qualified person who is willing to cooperate.

Senescence, arteriosclerosis, and similar changes, often closely associated with occupational disease, can be delayed, or largely prevented, by periodic physical examinations and proper medical and occupational guidance. The war which is now being waged against the venereal diseases should bear fruit in the prevention of heart damage due to syphilis and, even if syphilis itself be not prevented, its early and adequate treatment will greatly reduce the frequency of syphilitic disease of the heart and blood vessels.

The desirability of periodic medical examinations has been mentioned, but its well nigh supreme importance as a preventive measure demands further emphasis. There is a growing appreciation of the need for an annual examination of adults, but it is not realized that the need is even greater in children. Among the latter group there should be a thorough examination not less than twice a year, especially when the child is in apparent health as many of the chronic infections are so insidious that they may not become manifest until irreparable damage has been done.

Heart disease is generally insidious in its development and does not usually produce symptoms which attract the victim's attention until it has progressed so far that the heart has begun to fail in its capacity to meet the demands thrown upon it. When this stage is reached much less can be accomplished toward the prolongation of life and the relief of later suffering than could have been done had the disease been discovered in its earliest stages. It is essential, therefore, that the public be educated as to the enormous value of the discovery of heart disease in its very incipency, for when discovered then life may be greatly prolonged and suffering reduced to a minimum. Recognition of incipient heart disease is possible only by routine periodic medical examination, preferably with the aid of one trained in the field of heart disease, if any suspicious signs be found.

When heart disease is found to exist the measures to be employed for the prevention of its further development and of cardiac breakdown include the immediate and thorough removal of all discoverable foci of infection, the prevention of further infection, the maintenance of good nutrition, the provision for adequate sleep and rest, the improvement of the patient's general health and physical development, and often the guidance of the patient from an unsuitable into

a suitable occupation. The patient should also be educated in the recognition of the first signs of slight cardiac breakdown that appropriate steps may be taken immediately to prevent further damage and to restore the heart's capacity.

When decompensation, or cardiac breakdown, has taken place restitution is usually possible, but the most careful guidance is required to prevent the early recurrence of decompensation. The accomplishment of this by appropriate treatment, convalescent care, and by the adoption of the measures suggested in the preceding paragraph often permits the patient's return to a productive and useful life, while its neglect is prone to lead to chronic invalidism.

It is to the accomplishment of all of these ends upon a large scale, and especially in that portion of the community which must have more or less financial help, that the efforts of the Association for the Prevention and Relief of Heart Disease are directed. To these ends the Association has been and is now gathering accurate information upon all phases of heart disease to advance the development and application of measures of prevention and relief. It is searching out

and providing suitable occupations for persons with heart disease, and is providing vocational instruction for those who need it to secure a suitable occupation. It has promoted the establishment of many special dispensary classes for the care of heart disease, and has endeavored to improve the facilities for hospital and convalescent treatment. It is urging the provision of permanent institutional care for the diminishing group of hopelessly incapacitated cardiac patients. It is aiding in the provision for the school care of children with heart disease. Finally, it maintains a central bureau which serves as a clearing house for information relating to the prevention of heart disease and the care of cardiac patients. The constructive work is going forward through many channels, and it is confidently believed that as much can be accomplished in the reduction of sickness and premature death from heart disease as has been done in tuberculosis. Along with prevention through the rational control of predisposing contagions, conservation is effected through educating the individual; for physical and psychic stress is now fully recognized as causing much unnecessary waste of human life.

## Phthisis Deathrate Decreases

THE change in the deathrate from pulmonary tuberculosis indicated by a chart recently published by the Metropolitan Life Insurance Company has a wide social significance. Not only has the death rate been reduced but the age at which death occurs has been advanced to a point where the father has fewer young children incapable of self-support. In 1911 the maximum death-

rate occurred at age 38.8 years; by 1915 it had advanced to 40.5 years; in 1918 it was located at 42.6 years, and in 1921 at 44.8 years. This advancement in the age of death lessens the strain on public and private relief agencies and gives many thousands of children the benefit of home care which they would not have had if mortality conditions of ten years ago were in effect today.

# American Child Hygiene Association Meeting

WITH a broad vision of the tasks of the future, the American Child Hygiene Association agreed without a dissenting vote on Friday, October 13, 1922, to the proposed plans for union with the Child Health Organization of America. This was, beyond all question, the most significant act that the association has taken since its foundation more than thirteen years ago. This consolidation of the two leading groups of workers that are interested in the health of the children of the country will allow a unanimity of purpose, prevent a duplication of effort, and permit a singleness of plan that will begin with pre-natal work for the mother and end only when maturity is attained.

Mr. Holmer Folks, chairman of the special committee that considered the proposed consolidation, presented the report of the committee at the annual business meeting which was held in Memorial Continental Hall, Washington, D. C. The committee, which had been considering the proposed change since its appointment last June by the president upon the recommendation of the trustees, found that the proposed consolidation was practical but that the details of the union must be worked out in practice. The control of activities is to be centered in the hands of the executive director and the direction of the policies of the new society is to be in charge of a board of trustees elected from the general membership. This change does not, however, imply as radical a change as might be inferred. The detailed activities are to be carried on by small groups within the new membership. Those groups that have in the past been interested in the health of the children of school age will continue that work. The Child Health Organization of America has valuable experience in this field and the Child Hygiene Association has accumulated a fund of experience in pre-natal infant and pre-school work. The new arrangement will make no fundamental change in the scope of health problems against which the efforts of each group are directed.

## Hoover Reelected Head

In view of the association's reorganization President-elect Livingston Farrand declined to assume office at this time and Secretary Hoover was reelected to the presidency. The other officers include: Vice presidents Dr.

Fred L. Adair of Minneapolis and Miss Mary Arnold of New York city; secretary, Dr. Richard M. Smith of Boston; and treasurer, Corcoran Thom of Washington. Dr. Philip Van Ingen is chairman of the executive committee. The membership of the executive committee and the board of trustees is made up of men and women of equal authority and experience. Miss Julia C. Lathrop was elected an honorary member of the association.

In his presidential address Herbert C. Hoover, after announcing the forthcoming consolidation of the Child Hygiene Association and the Child Health Organization of America, made public a gift to the new unit from the Commonwealth Fund of

Herbert C. Hoover, who was reelected president of the American Child Hygiene Association, at its annual meeting in Washington, October 13, when it voted to merge with the Child Health Organization of America.

\$230,000 a year for a period of five years. This gift has been made for the purpose of financing demonstration programs in three American cities. It is proposed that one city shall be in the middle west, one in the far west, and one in the south and that each will receive the benefit of a \$300,000 program of child health instruction and help. The knowledge derived from these demonstrations will be available for all America and the experience gained will be for the use of all agencies through the great unified clearing house and advisory agency that the new unit will provide.

"The ideal to which we should

strive," Mr. Hoover said "is that there should be no child in America born under improper conditions, no child who does not live in hygienic surroundings, who ever suffers from under-nutrition, who does not have prompt and efficient medical attention and inspection, who does not receive primary instruction in the elements of hygiene and good health. It is the purpose of these associations to supplant ten policemen with one community nurse."

The speaker further stated that, while not directly embraced in the functions of the society, they aspired that every child should be free from deleterious labor, should participate in the great public school system, and have full participation in the joys of childhood. The past accomplishments in the field have been indicated by the fact that during the last four years infant mortality in the Birth Registration Area of the United States has dropped from 106 per thousand births to 78 in the present year. During this time the number of state bureaus devoted to child hygiene has increased from 28 to 46.

In continuing Secretary Hoover said, "the cause of children has no opposition with the American people except the opposition of ignorance." The object of the associations were defined as: First, that they stimulate appreciation of the service that can be done for children and the nation in the matter of health; second, that the enormous activity in America for the welfare of children and mothers shall be directed in a scientific manner and by scientifically trained men and women; third, that these applications of science shall reach every corner of the country and every child in it; fourth, that these efforts on behalf of children shall be built upon the solid rock of inspiring the local community to its responsibility, and not upon the shifting sands of over-centralization."

## New Pediatricist Needed —Holt

After commenting on the significance of the new organization, Dr. L. Emmett Holt, president of the Child Health Organization of America, stated that a new type of pediatricist was needed, one who has been trained not simply in a knowledge of the diagnosis and treatment of the diseases to which childhood is liable, but one who in addition knows the normal child—the conditions of growth, the prin-

ciples of nutrition, practical dietetics, the essentials of school inspection—who has been trained also in child psychology, who knows the fundamentals of child hygiene, mental and physical development. He should at the same time have the organizing and directing ability to put a scientific knowledge of all these subjects to practical use in a community.

Sir Auckland Geddes, British Ambassador, was among the distinguished speakers at the first evening session. That child health is a problem of international importance, that no race stock long remains pure and that the foreign child of today may be the citizen of tomorrow, were points stressed. "In an age of immigration and emigration the child health of any land is a matter of moment to all," he stated. "If people could be made to realize that the devastation caused by war in child life is greater than that caused property, they would not permit their nation or other nations to draw the sword. "Vital interests," the speaker continued, "are not bounded by frontiers."

Miss Elizabeth Fox, president of the National Organization for Public Health Nursing, made a plea for better training for the nurses going into child health work. She deplored the lack of knowledge in fundamental sciences, mental hygiene and normal nutrition. She was of the opinion that some of these topics were of much more importance than the mass of detailed anatomical knowledge that was in many cases of little use to the nurse.

Delegates from twenty-eight states, the District of Columbia, Canada, and the Philippine Islands were in attendance. Several foreign governments including Belgium, Mexico, Columbia, Uruguay, Costa Rica, Italy, Switzerland, and Poland appointed representatives to the convention. Mrs. H. W. Farnam one of the Belgian representatives read the following cablegram:

Many thousands of little boys and girls send you loving greetings and expressions of their gratitude for help given them in the darkest hours of the war by the Commission for the Relief of Belgium. Their gratitude distance and time can never dim.

### Nutrition Section Meets

At the general session on the training in nutrition needed for child health workers the principal speakers were Miss Flora Rose, School of Home Economics of the New York State College of Agriculture, Miss Edan White of the Merrill-Palmer School of Detroit, and Miss Emma Dolfinger of the Child Health Organization of America, New York City.

Miss Dolfinger said that nutrition work had demonstrated its value in the public school program but doubt was still felt as to the most effective use that could be made of the nutrition worker's time and training. All three speakers emphasized the need of giving the nutrition worker more training in educational methods. It would also seem from the papers and discussion that there might be some question as to the adequacy of the training in fundamental sciences that the workers receive.

Dr. Richard M. Smith of Boston, Dr. Albert D. Schlink, medical director of the Day Nurseries in Cleveland, and Dr. Florence L. McKay presented papers at the session on the problem relating to the pre-school child. Dr. Smith said that the infants and the school children had a definitely worked out program while the pre-school child, although not entirely neglected, lacked the benefits that would come from a definite and standardized procedure in this work. "The child in a large family with both parents living but with the budget hardly adequate for food and lodging is in the worst class," stated Dr. Schlink. "It is among these children that we find the prize babies of the Infant Hygiene Department; but they are thrown out on the world at the end of their infancy. On entering the first grade of school their physical defects are legion." Dr. McKay brought out the point that while movements of a similar nature had begun in the city and worked toward the country districts, the work for the pre-school child had worked in the reverse direction.

### Private Organizations

Bailey B. Burrirt, general director of the Association for Improving the Condition of the Poor, New York City, Courtenay Dinwiddie, executive secretary of the National Child Health Council, and Raymond Clapp, associate director of the Welfare Federation of Cleveland, presented papers at the general session on the administration of private child health organizations. Mr. Burrirt stated that any program for child health should begin an earnest endeavor to give complete pre-natal service. The supervision should continue throughout infancy, and after leaving the baby health stations and before entering school a child should have at least two complete physical examinations. Following the school hygiene program should be an industrial child hygiene program which involves getting the child suitably started on its industrial

career. Mr. Burrirt illustrated his address by telling of the work done by his organization at the Mulberry Health Center, New York City.

Mr. Dinwiddie declared that "the threads of a broadly conceived plan of service for children must run not only through every phase of the child's work, play, and life in general, but must lead straight to those conditions and forces in his home and community in which he lives, which are moulding his body and his mind, whether for good or for evil."

Mr. Clapp spoke of the various methods of raising funds to carry on the work of private health organizations. He advocates a straightforward appeal to the public for the necessary money. His illustrations were drawn from the plan used by the Welfare Federation of Cleveland.

### Nursing and Social Work

At the session of nursing and social work Miss Kathleen Edwards, supervisor of the Nursery School Demonstration at the Columbia University Summer School Session, told of her work in the nursery school movement both here and in England. She stated that the time to learn right social, mental, and physical habits was between the ages of two and four years. She described the day of work and play in a nursery school and to a most interesting talk added a series of lantern slides.

At the same session Miss Gertrude E. Hodgman, educational secretary of the National Organization for Public Health Nursing, spoke on the educational standards for child welfare nurses and Miss Winifred Rand, director of the Boston Baby Hygiene Association, discussed the behavioristic problems of the pre-school age. Miss Hodgman said that the nurse must have a knowledge of routine procedure and standard methods, that she should know nursing and the broad background of science on which it is founded, and that she should have in addition a certain attitude of mind that would enable her to handle the different problems given her.

This idea of adaptability was one of the key-words of the convention. It was mentioned in many of the leading papers and spoken of throughout the discussions. The variety of situations due to the nationality of the patients, the geography of the country, the economic status of the community, and similar environmental factors are continually bringing the nurse face to face with new situations for which her previous training has not fitted her. The only possible solution lies

in a basic knowledge of the fundamental scientific facts in order that the nurse can build up a specific solution from the general information she possesses.

Miss Rand dwelt on the folly of bending all energies to the production of a healthy body and neglecting to a great extent the mind of the child. The habit clinic, the speaker said, is of inestimable value in seeking to interpret the actions of childhood.

### Maternal Welfare Problem

The morning session of the final day of the convention was devoted to the problems of maternal welfare. In speaking of the service of an obstetrical clinic to the community, Dr. Arthur M. Morse of the Yale School of Medicine, stated that such a clinic in order to get the best results should be a department of a general hospital. Provisions should be made for a pre-natal clinic, an out-patient department, and a post-natal clinic. He spoke of the difficulty of getting adequately trained nurses for obstetrical work. Dr. Morse strongly recommended a single unit for the care of all diseases of the female reproductive tract, stating as his reason for this belief that with the exception of gonorrhoea of the uterus, practically all diseases of the reproductive organs are associated with child birth and are preventable.

Dr. W. J. Bell, pediatrician to the Maternal and Child Welfare Bureau of the Ontario Provincial Board of Health, in his paper on maternal mortality made two points; first, that maternal mortality is a large and serious problem; second, that the health effort is showing no appreciable effect in reducing the maternal mortality death rate, and that in Ontario it seems to be increasing slightly. The speaker attributed the low rate in England and Wales to the legal requirements relating to midwives and the health education of the mothers. In the discussion that followed Dr. Louis I. Dublin brought out forcefully the fact that all the effort of an excellent pre-natal program could be ruined by poor obstetrical service.

Miss Grace Abbott, Chief of the Federal Children's Bureau, spoke of the administration of the Sheppard-Towner Act. All the forty-two states that have accepted the provision of the act feel that the major responsibility rests on them. Fifteen states are to license, instruct, and control midwives. By no means the least benefit that has resulted from the act is the nation wide interest in maternal and infant welfare.

The last meeting of the convention was a medical session at which Dr. Borden S. Vceder, Washington University, St. Louis, discussed child hygiene in relation to the private physician. He stated that to be effective an infant or child welfare conference must limit its activities to the well child. The best supervision depends, according to the speaker, on an intimate knowledge of the home life of the family. Furthermore, supervision will gain much if it is under the same physician throughout the life of the child. The private physician is therefore, the best man to exercise this function. The speaker concluded, "The welfare conference has definite defects but it has given results. Until the ideal of supervision by the private physician arrives the welfare conference has its place."

Dr. William H. Park, Director of Laboratories, Department of Health, New York City, said that the Schick test was reliable only when the amount of toxin did not exceed one fortieth of a minimal lethal dose for a guinea pig, and when given intracutaneously. Dr. Park stated that at five months 88 per cent of children were found to be immune after toxin-antitoxin immunization.

The relation of nutrition to teeth was considered by Dr. Clarence J. Grieves, Chief of the Dental Clinic of Johns Hopkins Hospital. The nutrition of the mother during the last seven months of pregnancy was stated to be a matter needing the most careful attention. In regard to the dietary requirements for the formation of bone and teeth, Dr. Grieves was of the opinion that too often the solubility and absorbability of the mineral substances given were not carefully considered and thereby the expected results were often wanting. He also stated that nutritional disturbances that effect the bones do not always affect the teeth and warned against drawing parallel conclusions.

The finest of Washington weather favored the convention and an informal gathering at the Coreoran Gallery of Art, a tea at the Federal Children's Bureau, a visit to the Arlington Health Center, and an inspection of the Children's Hospital added variety to the very complete program.

A celebration of the one hundredth anniversary of the birth of Louis Pasteur will take place in Philadelphia, December 27, 1922. According to tentative plans a meeting will be held in the afternoon at the Academy of Music followed by a banquet at the Bellevue Stratford Hotel.

### New York's Child Health Program

Although rejecting the benefits of the Sheppard-Towner Act, New York state has provided for the health of its mothers and children by the passage of the Davenport-Moore Act providing for an appropriation of \$130,000 for work in the state by the Commissioner of Health through the Division of Maternity, Infancy, and Child Hygiene, of which Florence L. McKay, M.D., is director.

The specific functions to be carried out under the law include (1) making surveys and studies of local conditions influencing the health of mothers and children; (2) advising localities as to providing adequate care of mothers and infants and children to whom such care is not otherwise available; (3) holding health consultations for mothers and children in the rural districts in cooperation with local health officers and other physicians; (4) instructing local public health nurses in the hygiene of maternity and infancy; (5) making available to mothers, through instruction by physicians, nurses, and publications, information concerning the hygiene of maternity and infancy; (6) supervision and training of midwives; (7) prevention of blindness in infancy; (8) care and rehabilitation of crippled children not otherwise provided for; (9) public instruction by means of moving pictures and lectures and other methods regarding preventable conditions affecting infant and maternity deaths.

The Act aims primarily to stimulate localities to undertake their own work for mothers and children through their own agencies and to help such localities in organizing and starting this work.

To secure the cooperation of the physicians and health officers of the state, regional consultants of recognized standing and in pediatrics or obstetrics have been appointed in various sections of the state. These regional consultants will disseminate information as to the plans of the state department in carrying out the work.

The Act does not make provision for financial subsidies for local communities but supplies various types of health promotion service to localities, among them an organization service, a nursing service, medical service, and nutrition service.

With the work extending over the state and not intensively in any one locality, it is not expected that results in the lowering of mortality rates will be noticeable for some time.

# The Prevention of Simple Goiter in Man

BY O. P. KIMBALL, M.D., CLEVELAND CLINIC, CLEVELAND, OHIO.

THE problem of goiter is a very old one. It is mentioned in the oldest medical literature and is frequently referred to by the Roman historians. The Arthorva-Veda—a collection of ancient Hindu incantations dating back to 2000 B.C.—contains extensive exorcisms for goiter.

The term simple goiter or endemic goiter means just one thing—enlargement of the thyroid gland. Simple goiters may develop in any locality, on land or sea, but in certain districts, the incidence of goiter and cretinism has continued at such a high level for generations, involving all domestic animals as well as humans, that it has come to be considered characteristic of or endemic in those localities.

That there are definite goiter districts has been common knowledge for centuries. The most noted of these is in Southern Europe, comprising Southern France, Switzerland, Southern Austria and Italy. But the incidence of goiter and cretinism is even higher in Southern Asia and Eastern Mongolia on the Gobi desert; i. e., Southern China, the Plateau of Thibet, and Himalayan India. In South America the whole Andes region is an endemic goiter district and on the Peruvian plateau goiter and cretinism have probably reached their highest incidence. In North America, the Hudson Bay district, all of the Great Lakes basin, the basin of the St. Lawrence river and the Pacific Northwest, comprising British Columbia, Alberta, Southern Alaska and the states of Oregon, Washington, Idaho and part of Montana are endemic goiter districts.

The end result of a severe, continuous goitrous condition is myxoedema in the individual thus affected, and cretinism in the next generation. Either through its control over cellular metabolism alone, or possibly by some direct coordination with the secretion of the ovaries, the thyroid secretion plays an all important part in the normal growth and development of the adolescent period. Congenital goiter is due to lack of maternal thyroid secretion during pregnancy and proves the importance of the thyroid secretion during this period. The three periods of life during which goiter is likely to develop are fetal life; pregnancy; and

adolescence, the extra demand for thyroid secretion at puberty and during pregnancy being sufficient explanation of the development of so many goiters at these periods.

## Treatment with Iodin

Iodin in some form has been used for centuries in the treatment of goiter. It was first knowingly used in 1820 by Coindet and has been used extensively ever since. In 1895 Baumann discovered that iodine is a constituent of the normal thyroid. In 1907 Marine emphasized the fact that iodine is essential for the normal function of the thyroid and also, that in active hyperplasia of the gland, the iodine store is reduced, the decrease in iodine content being proportional to the degree of hyperplasia. In mammals, e. g., the dog, sheep, ox, pig, rabbit, cat, and man it has been shown that normal thyroids contain the highest percentage of iodine per weight of the gland, averaging 0.2 per cent with extremes of 0.1 per cent and 0.5 per cent. It has also been demonstrated that as soon as the iodine content of the thyroid falls below 0.1 per cent, active hyperplasia of the gland begins. In other words, functional hyperplasia, and therefore goiter cannot develop, at least in the mammals above mentioned, if the iodine content of the thyroid is maintained at a minimum of at least 0.1 per cent.

The first practical application of prevention of goiter on a large scale was made in the fish industry. In 1909, endemic goiter was causing so much trouble and loss at the Pennsylvania State fish-hatcheries, that the state commissioners were ready to abandon the industry, under the apprehension that the disease was cancer. The researches of Drs. Marine and Lenhart soon demonstrated that it was only a problem of endemic goiter caused by two factors—(1) over-crowding and (2) the exclusive use of an artificial food which was almost totally devoid of iodine. The whole problem of endemic goiter in these hatcheries was solved by changing the over-crowding and by adding a very small amount of iodine to the food. Marine's theory that "simple goiter is the easiest known disease to prevent" was based on this work, together with other animal experimentation.

By 1915 the active principle of the

thyroid had been isolated in crystalline form by Kendall of the Mayo Clinic, who found also that any substitution for iodine in this compound completely destroyed its physiological activity.

We know of no field in preventive medicine or public health in which more work had been done and in which such complete evidence of the possibility of absolute prevention, and the impossibility of ill effect, had been secured as was the case with endemic goiter at the time when Dr. Marine and the author proposed to control the development of goiter in school girls. Yet there was considerable criticism of the plan of giving iodine to girls promiscuously. Some predicted many cases of iodine rash; others thought a great number of the girls would develop exophthalmic goiter. Both of these possibilities were considered throughout the work done in the Akron public schools. They were explained to the principal of each school and the teachers were asked to record any untoward effect. During three years more than ten thousand treatments were given and the sum total of ill effects included but eleven cases of mild iodine rash. Six of these were so mild that the girls continued to take the treatments. The other five were advised to stop the treatments, and in each case the rash promptly disappeared. From these data it would appear that a mild iodine rash may occur in approximately 0.1 per cent of cases under treatment.

In the practical application of the idea of prevention, we chose the public schools for two reasons—(1) The children are in the adolescent age, the most important period in the development of goiter. (2) The public school group furnishes the best census of goiter in any community, and makes it possible to carry out, through the school organization, the most expedient, economic and practical plan of prophylaxis and education.

In October, 1916, the superintendent of schools of Akron, with the full support of all the school authorities if the local medical society sanction the work. After the matter had been explained to the Summit County Medical Association, this body, in a regular session, voted to send the following message to the

school board: "The idea of prevention of goiter, as outlined, can do no harm and may do good. We are in favor of seeing it carried out." The school board authorized the superintendent to call upon Dr. Marine and the author to make a survey of goiter among the school children of Akron and to carry out any plan of prevention we saw fit.

In April, 1917, an examination for thyroid enlargement was made of all girls from the fifth to the twelfth grades, inclusive. The boys were not examined because of the relative infrequency of goiter in boys. The result of each examination was recorded on a special individual card which on one side had space for the pupil's name, school, age, grade, and for the tabulations of four thyroid examinations. On the back of this card was space for the recording of eight series of prophylactic treatments given by the teacher. This goiter card was attached to the school record and was transferred whenever a girl changed schools. In no other way could we keep track of so many cases over so long a period of time.

The results of our first examination of all girls from the fifth to the twelfth grade inclusive are shown in Table I.

TABLE I

Normal thyroids.....	1688 or 43.5 per cent
Slightly enlarged thyroids....	1931 or 49.9 per cent
Moderately enlarged thyroids .....	246 or 6.3 per cent
Markedly enlarged thyroids .....	7 or 0.3 per cent
Adenomas.....	39 or 1.0 per cent
Total .....	3,872

In April, 1917, the first prophylactic treatment was administered to more than 1,000 girls who had elected to take it. No girl was urged and no one was permitted to take the treatment unless she had a written permit from a parent.

Two quart amber bottles were filled with the school's drinking water and sufficient sodium iodid was added so that one teaspoonful would contain 3 grs. of sodium iodid. This was administered daily at the school by one of the teachers at a convenient time—morning or evening. All the girls in the building taking the prophylactic treatment would line up and as individual drinking cups were supplied they would fill their cups with the amount of water they wanted to drink, the teacher would add a teaspoonful of the iodid solution and the pupil would drink it immediately. By this method the administration of the prophylactic dose consumed only a

few minutes each day for a period of two weeks each spring and fall.

TABLE II  
SUMMARIZED RECORDS OF PUPILS TAKING AND NOT TAKING PROPHYLACTIC TREATMENT

	Taking		Not Taking	
	Totals	Percent	Totals	Percent
Normal:				
Unchanged.....	906	99.8	910	72.4
Increased....	2	0.2	347	27.6

Unchanged....	477	41.9	698	72.8
Increased....	3	0.3	127	13.3
Decreased... 659		57.8	134	13.9
Moderately Enlarged:				
Unchanged....	29	20.3	57	64.0
Increased....	0	0.0	21	23.6
Decreased... 114		79.7	11	12.1
Total .....	2,190	....	2,305	....

In November, 1917, a second examination of all girls from the fifth to the twelfth grade inclusive was made. In all 4,415 cases were examined, 1,772 of which were new cases. Of the 2,643 girls examined previously, 764 had taken the prophylaxis during the preceding six months and 1,879 had not. As was published then, among the pupils taking iodine there was not a single instance in which a normal thyroid had increased in size while among those not taking iodine, 26 per cent of the glands designated as normal at the first examination, showed definite enlargement—some already having become moderately large goiters. But more than a prophylactic action was shown by the results—just one-third of the so-called "small goiters" had disappeared, and one-third of the "moderate goiters" had decreased 2 cm. or more.

In November, 1918, a third examination of 4,277 girls was made. In October 1919, 5,520 individual examinations were recorded, 9,967 different girls having been examined during the entire period.

Effect of Treatment

The effect of the treatment is shown in Table II in the columns marked "unchanged" and "increased." Since examinations were made only once each year, each record must cover at least one year while many records extended over a period of two and one-half years. Of the girls with normal thyroids at the first examination who did not take iodine, 347 or 27.6 per cent showed enlarged thyroids at the final examination; while of those that were normal at the first examination and took the iodine as prescribed, the thyroids became enlarged in only 2, or 0.2 per cent. These two cases were investi-

gated and we found that each case developed a small goiter in spite of the prophylactic treatment given. The thyroid of the first case, a girl 16 years of age, had been classified as normal on three successive examinations while on the fourth examination it was classified as slightly enlarged although she had taken the iodine each spring and fall during these periods. A special examination verified the fact that the thyroid had become enlarged, but in addition it disclosed very large and infected tonsils, decided evidence of infected adenoids with enlarged cervical lymph glands, with a history of frequent attacks of tonsillitis during the preceding two years.

The second girl, 15 years of age, had been watched for a year, had taken the prophylactic treatment twice and apparently had developed a small goiter during the year. On special examination the presence of an enlarged thyroid was verified, but this girl although fifteen years old was in only the third grade. Careful inspection revealed the presence of Hutchinson's teeth, a depressed nasal arch, and the fact that she was almost blind from interstitial keratitis. This was a case of neglected congenital syphilis.

Among those whose thyroids were classified as slightly enlarged at the first examination and in those not taking the prescribed iodine, the thyroids underwent further enlargement in 127 or 13.3 per cent; while in those taking the prescribed treatment, in only three or 0.3 per cent did the thyroids become more enlarged. Two of these three girls were re-examined on January 13, 1920 and the increased enlargement was verified. One of these three had a chronic infection of the tonsils with recurrent attacks of tonsillitis during the last year. In another of these three cases, superficial inspection failed to show any pathological condition. The third girl was not present for this final examination. These five cases were the only instances among 2,190 pupils taking iodine in which the thyroid gland showed enlargement. Of the 2,305 cases not taking iodine, 495 showed thyroid enlargement. Of the group with small goiters, taking iodine, 659 or 57.8 per cent of the thyroids returned to normal, while of the same group, not taking iodine, according to our records, 5,134 or 13.9 per cent returned to normal. However, we know that there is an error in the last figure, for many girls who were not taking iodine under the school jurisdiction were receiving it in some form

from their physician. No attempt has been made to estimate this error. In the practical application of the preventive treatment, one must keep constantly in mind the three periods during which simple thyroid enlargements most commonly occur: viz., (1) the fetal period; (2) the adolescent period; and (3) the period of pregnancy.

The prevention of goiter in mother and child is as simple as the prevention of the goiter which develops during adolescence.

Practically, it would seem that the responsibility for the prevention of fetal goiters and of the goiters of pregnancy belong to the individual members of the medical profession whose efforts should be supplemented by public education.

The prevention of goiter in the adolescent period, on the other hand, should be a public health measure under state, county or municipal control. The existing systems of organization of the schools, public and private, are sufficient to handle all the details without additional aid or expense. Education of the pupils in the value of this prophylactic measure could be combined with the actual administration of iodine so that after leaving school they could continue the treatment, if necessary. In industrial medicine, physicians could render an important service in this field. As thyroid enlargement is approximately six times as frequent in girls as in boys, each community must decide whether it will include both sexes in its endeavors to prevent goiter. Likewise, as to the age of beginning and stopping the use of iodine, that must be determined by the age of occurrence of goiter in each section. In this climate probably the maximum of prevention, coupled with the minimum of effort, would be obtained by giving it between the ages of 11 and 17 years. As applied to our school system this would mean beginning with the fifth grade.

The prevention of goiter in individuals with other diseases, or in those residing in such extremely goitrous districts as some of the glacial valleys of Alaska and British Columbia and certain districts of the Alps and Himalayas, might require larger amounts of iodine in normal individuals than those indicated above.

The system of treatment outlined above has been used successfully in several different towns in Ohio, in some Cleveland factories, in plants of the National Lamp Works, and by Prof. R. Klinger in Zurich. The ease with which goiter prevention can be

applied as a public health measure makes possible the ultimate control of endemic goiter.

The same imagination which saw through the theory to the practical

results of the prevention of goiter can now see, a few generations hence, the extinction of endemic goiter and cretinism in every civilized nation in the world.

## Red Cross National Convention

**E**NTHUSIASTIC endorsement by the delegates to the National Red Cross Convention of the action of the Central Committee in authorizing a relief campaign for the sufferers and refugees in the Near East, marked the opening session of the annual meeting held in Washington, October 9-12.

In an address on the ideals of the League of Red Cross Societies by the General Director, Sir Claude Hill, credit was given America for the creation of this international agency. The noted visitor spoke with feeling of the late Henry P. Davison as the originator of the peace time program of the Red Cross, and as a man to whom vision had been given to see that the volume of preventable suffering in time of peace was at least as great as that in time of war. "He had," the speaker declared, "the courage to hope that the world would seize the opportunity which had been afforded by the development of a peacetime program of work for the Red Cross Societies to work harmoniously on a cooperative basis toward mutual help and self-betterment."

In discussing specifically the principles of the League, Sir Claude said in part, "If the ideal for which the League was launched be properly studied and understood, it will be found to amount to this: The organization of the National Red Cross Societies the world over to furnish mutual help, suggestion, advice, and experience to one another, aiming primarily at permanently improved health and improved social and economic conditions, and, in the second place, consequentially at reconstruction and restored sanity of mind as well as body. The founders of the League of Red Cross Societies would help forward the attainment of this great objective, and I believe I am correct in saying that your distinguished chairman, Judge John Barton Payne, who is also our chairman, cherishes, and believes in and persists in the same faith."

During a speech on volunteer service at the plenary session of the convention Miss Mabel T. Boardman, Secretary of the American Red Cross, presented her views on the

purposes outlined in, and the powers granted by the present charter. She intimated that the society is exceeding its obligations and may have "lost its bearings."

In an informal discussion later in the session on some of the questions raised by Miss Boardman's address Judge Payne said: "Neither the Central Committee nor the chairman feel any such restrictions under the provisions of the charter directing the Red Cross to take means to prevent disaster, disease, calamities, and so on. There is authority and warrant in the charter for carrying on any service which renders disease, epidemics, disasters, or any thing of that sort, less frequent or in other words, tends to prevent such calamities.

"Public health nursing, which is mentioned in the question asked, is one of the things to which the Central Committee attaches a great deal of importance. The only limitation we have felt on that subject is—I do not believe, and I speak for the Central Committee in this, too, I think—that the Red Cross should be in competition with other health or charitable organizations; and that is what I understood Miss Boardman to mean this morning.

"We should not lose ourselves in our local obligations. If there is in our localities some other organization which ought to do that work, it should do it. With reference to public health, whenever we start a public health nurse in a community, it is pioneering. The moment that the town or county is educated to the point of taking over the work we should use every effort to bring about the taking over of that activity by the community, because we regard it as a community obligation. But since there is no other agency known that is prepared to do that pioneer work, we regard it as a very important part of the Red Cross program."

The City of New York has created a new division of its department of health, namely, the Division of Veterinary Inspection. The division is charged with the duties of investigation and of enforcing veterinary activities.

# Automobile Accidents in the United States\*

BY AMBROSE RYDER AND H. P. STELLWAGEN, NATIONAL BUREAU OF CASUALTY AND SURETY UNDERWRITERS, NEW YORK CITY.

THE automobile caused the death of 13,000 people in the United States during 1921, an average of over 35 per day and an increase of nearly 1,000 over 1920. About 75,000 persons meet their death every year in accidents of one sort or another. The automobile then, is responsible for over one-sixth of all deaths by accidental causes, and, therefore, stands very high among the preventable causes of accidental death.

A tabulation of traffic fatalities in 50 American cities shows a total of 3,837 automobile deaths as compared with 3,637 for 1920. The 1921 automobile death rate for these cities was 155.1 per million population, an increase of 3.6 per cent over the 1920 death rate of 149.7. The data for those cities, which are scattered over the entire United States and which aggregate a population of 24,735,383, may be considered characteristic of the whole country. It is, therefore, reasonable to assume that the percentage increase in the 1921 automobile death rate over the 1920 rate for those cities was the same as that for the entire United States. The 1920 rate for the continental United States as reported by the United States Bureau of the Census was 104.05 per million population. On the basis of a 3.6 per cent increase this figure becomes 107.8 for 1921. This rate applied to the estimated population of the United States as of July 1, 1921 of 107,833,284 produces a total of 11,624 deaths from automobiles in the United States for 1921.

This figure does not include automobile fatalities which occurred at railroad grade crossings. According to the classification scheme used by the United States Bureau of the Census and by the Health Department of the fifty cities whose data are included in this report, all deaths caused by collision between automobiles and heavier vehicles, such as railroad trains and interurban trolleys, are assigned to the heavier vehicles. This statistical classification notwithstanding, the automobile must take the blame for most automobile accidents at railroad crossings. Actual observation on a large scale has proved that few motorists observe ordinary precaution when approaching

grade crossings, such as slowing down to moderate speed and looking and listening before crossing the tracks.

According to statistics compiled by the Interstate Commerce Commission there were 1,702 persons killed at railroad crossings in 1921. About 75 per cent of these, or 1,276, were occupants of automobiles. These 1,276 deaths added to the 11,624 as calculated on the basis of the United States Bureau of Census data give a total of 12,900 and the meager allowance of an even hundred deaths for collision between automobiles and street cars and interurban trolleys brings the figure up to 13,000.

The number of people injured (not killed) in automobile accidents cannot be estimated very closely because of the scarcity of data on the subject. However, an approximation of such injuries may be made from the following. In the state of Massachusetts, for the six year period of 1915 to 1920 inclusive, 2,608 people were killed in automobile accidents, and 68,671 injured or 26.4 injuries for every fatality. In the state of Iowa, from 1916 to 1919, 14,200 people were injured and 920 were killed; a ratio of 15.4 to 1. Naturally the ratio of injuries to deaths would be lower in a state like Iowa where accidents are proportionately more severe, than in Massachusetts where the congestion of population in the cities accounts for more minor accidents. According to figures compiled by the Police Department of New York City, 848 persons were killed and 20,461 injured in that city during 1921, making 242 injuries for every death. It is reasonable to suppose that the country-wide proportion between injuries and fatalities is between 20 and 24 to 1. This means that there were at least 200,000 people injured in automobile accidents in the United States during 1921, and possibly as many as 300,000.

## Damage to Property

Property damage done by automobiles is even more difficult to estimate. Only a few cities and practically no states have kept statistics on automobile accidents involving damage to property. However, a rough approximation of the damage done by automobiles can be made on the basis of the statistics of casualty insurance companies as compiled by the National

Bureau of Casualty and Surety Underwriters. These statistics show that there are approximately four property damage accidents to every accident involving personal injury, and that each accident results in about \$50 damage to property other than the car responsible for the accident. It may be assumed, therefore, that there were over 1,000,000 automobile property damage accidents in the United States during 1921, costing at least \$50,000,000. This figure does not include loss through fire and theft nor does it include much of the damage sustained by the automobiles themselves.

The increase in the automobile death rate of 149.7 to 155.1 per million population came about in the face of an actual decrease of 4.8 per cent in the death rate for all vehicles. From the following summary it will appear that the death rates for street railways and steam railways fell off considerably in 1921. On the other hand, the "other vehicles" classification, which includes for the most part horse drawn vehicles, motorcycles and bicycles, increased somewhat.

TABLE I TRAFFIC FATALITIES IN 50 AMERICAN CITIES (RATES PER MILLION POPULATION)

	No. of deaths		Rates		Over 1920
	1921	1920	1921	1920	
Automobile	3,837	3,637	155.1	149.7	3.6
Street Railway	601	772	24.3	31.8	-23.6
Steam railway	841	1,077	34.0	44.3	-23.2
Other vehicles	321	293	13.0	12.1	7.4

All vehicles... 5,000 5,779 226.4 237.9 -4.8  
\*Minus sign (-) denotes decrease.

Although the automobile death rate for Los Angeles is about twice that of New York City when based on population, it is only one-third as large when calculated on automobile registration. Cleveland's death rate based on population is a great deal higher than that of Boston, but only about one-half the size of the latter's on the basis of automobile registration.

Having determined something of the extent of the automobile accident problem, the next step is to find out the causes that have produced the existing situation. Despite the scarcity of information on the causes of automobile accidents, some definite conclusions may be arrived at from the following data:

The Travelers Insurance Company of Hartford, Conn., recently analyzed 200 fatal and 200 near fatal automo-

\* Read before the Public Safety Section, Eleventh Annual Safety Congress, August 31, 1922.

bile accidents. The analysis produced the following information: 131 accidents were caused by too much speed; 64 accidents were caused by careless operating; 40 accidents were caused by drunken operators; 40 accidents were caused by children darting in front of cars; 30 accidents were caused by cutting in ahead of traffic; 12 accidents were caused by insufficient lights; 9 were caused by defective brakes; 7 accidents were caused by dazzling lights.

The Massachusetts Department of Public Vehicles tabulated 521 fatal and 390 near fatal automobile accidents for 1921. In 292 cases, the cause of the accidents were given as "too fast for conditions," and in 150 cases, the cause was "careless operation." These two causes led all the rest.

In Maryland, the State Roads Commission investigates all automobile accidents and plots them on a highway road map of the state. From this map it is evident that most of the accidents occur, not in the congested parts of the state, not on the

sharp curves and deep grades along the roads, but on the long straight stretches of improved roadway which invite the motorist to speed up his machine.

All this evidence points to the fact that the chief cause of automobile accidents is the careless and reckless motorist. Of course, the child darting in front of an automobile, and the pedestrian running across the street, are responsible for many accidents, but the chief offender is the motorist who jeopardizes human life through sheer thoughtlessness or criminal recklessness.

A striking example of what can be accomplished in the reduction of automobile accidents by taking drastic action against offending motorists was furnished by the state of Massachusetts. In 1920 there were 21,086 injuries in the state from motor vehicle accidents, and in 1921, the figure was 11,487, a decrease of 45 per cent. During 1921, 4,899 licenses were revoked. Evidently the revocation of these licenses had a stimulating effect on careful driving.

present age will be of little benefit to posterity if there is a decline in the native quality of the race. It would be disastrous to hand over a more perfect and complicated governmental machine to inferior engineers.

One-seventh of the present generation will be the parents of one-half of the next. Therefore, two generations of selection, natural or designed, would completely transform the character of a nation. Is this seventh composed of the best men and women that we have?

This is what is going to determine whether civilization shall advance or retrograde. Galton's ideal of eugenics may be too much in advance of the age to be practical, but at least something could be done to awaken the people to the imminent dangers of dysgenics.

Plans are being formulated and blue prints executed for the organization and construction of the medical center which has been created by an alliance between the Medical School of Columbia University and the Presbyterian Hospital, New York City, under the direction of Dr. C. C. Burlingame, executive officer of the administrative board. The plans include a new College of Physicians and Surgeons, a new Dental School, a new Presbyterian hospital, new Sloane hospital, and new Vanderbilt clinic. Hospitals will probably be built for special types of cases.

## Evolution Working Backward

THE old theory of one-way evolution, in which each successive generation was supposedly higher and better than the old and progress toward perfection of type was certain and uninterrupted, would be a comfortable belief if it could be held in face of cumulative facts asserting that like produces like. Once farmers planted the nubbins of their corn and the potatoes that were too small to sell. Now they know better. They cut up their finest potatoes to plant and their seed corn is pedigreed as carefully as a Colonial Dame. The result is a doubled yield in potatoes richer in starch and corn richer in proteins.

But science has been slower in effecting an intelligent control of human life, and there is need for haste if the progress of the race is to be assured. The age of instinct is passing, the reign of reason has not come. Man has by sheer pressure of the circumstances of his life developed up to a given point. He has now succeeded in easing the pressure. Will he be able to go forward rationally, of his own free will, or sink back until he falls under the sway of the blind and merciless struggle for existence?

Discussing this question, the *Scientific Monthly* comments on recent

sociological investigations in Great Britain as follows:

A decrease in the birth rate is not necessarily a misfortune to a country. Very likely the British Isles have now all the population they can support in comfort under present economic conditions. The alarming thing about it is that the breeding is from the poorest stock instead of the best. Whatever objective standard one may take, this is true. A statistical study of the population of Great Britain showed that in the districts where there was the most overcrowding, the cheapest type of labor, the lowest degree of culture and education, the highest percentage of pauperism and lunacy, the greatest criminality and the highest death rate from tuberculosis and infantile diseases, there the number of children was greatest in proportion to the possibly productive wives. It is a clear case of the survival of the unfittest, the reversal of evolution. No race can maintain its efficiency and virility against such reactive forces.

The future of a country depends ultimately upon the character and ability of its people. Increase of wealth, advance of science, improvement in education, discoveries in sanitation, just social conditions, all the achievements and hopes of the

Making health attractive to the country's youth is the business of Cho Cho, U. S. Public Health Service health clown, who is shown here weighing one young citizen on the steps of the Treasury at Washington.

# Red Cross in Western Russia and the Baltic

## The Program for a Constructive Demonstration of Child Health Work

By J. H. M. KNOX, JR., M.D., FIELD MEDICAL DIRECTOR, AMERICAN RED CROSS, PARIS, FRANCE.

THE Commission to Western Russia and the Baltic States was organized in Berlin under Lieut. Col. Edward W. Ryan, who had served continuously with the American Red Cross since 1914. The Commission consisted of a group of physicians and young business men familiar with handling supplies, most of whom had had active army service. It started from Berlin for Latvia in October, 1919, carrying its supplies in a long line of motor trucks. The job of the Commission, like that of similar American Red Cross commissions sent at this time to other countries of war-stricken Central Europe, was to help relieve the widespread destitution and distress resulting from the war. Almost at once the convoy met with actual fighting between the German Iron Division and the Latvians for the possession of Riga, and shortly after it took part in the struggle in the area of Dvinsk, which resulted in driving the Bolsheviks out of Latvia. At the same time the Bolsheviks were expelled by the Russian Northwest Army from Esthonia, and driven to within five miles of Petrograd, when they in their turn were defeated and forced back into Esthonia.

In all this period of fighting the American Red Cross, often under fire, was active in caring for the wounded of all the armies. A severe epidemic of typhus fever broke out in the spring of 1920 among the troops of the Russian Northwest Army, almost without rations and crowded in unhealthy barracks in Esthonia. The disease threatened to involve the whole country but was checked in six weeks through the effective measures introduced by Colonel Ryan and carried out by the American Red Cross Commission. In this splendid piece of public health service two of the commission succumbed to the disease. In the year that followed the work of the commission was one of general relief to the thousands of refugees who were pouring into Finland and the other Baltic States from Bolshevik Russia. Many dispensaries were started in connection with the American Relief Administration and nearly all existing hospitals and homes were

materially aided. It is fair to say that the generous and timely assistance of the American Red Cross at this critical period greatly helped these newly-formed countries to weather the storm and perhaps made it possible for them to establish their national existence.

In May, 1921, those in charge of the American Red Cross work in Europe decided that a general relief program was no longer needed, and directed that the activities of the various commissions should be devoted to a constructive program of child health work. The Commission to Western Russia and the Baltic States was asked to concentrate its work in the three states of Esthonia, Latvia and Lithuania. Nearly 150 clinics for children were organized throughout these countries, usually in connection with the American Relief Administration feeding stations already established. Each clinic was conducted by a native doctor who was in attendance for two hours three times a week, and two native nurses who spent their time out of clinic hours in visiting the families in their homes, under the doctor's directions. The choice of these doctors and nurses was made with the assistance of the welfare department of the several governments. Although, of course, a large proportion of minor ailments, including various degrees of anemia and malnutrition, were treated in these clinics, a great amount of good was accomplished. Many of the children so reached would not have had any medical supervision otherwise. The records show that nearly 85,000 children attended these dispensaries. In Riga alone, in three dental clinics 12,000 children have received dental care free of charge.

### Child Health Program

The child health program in the Baltic States was greatly strengthened by the advent, during the summer and fall of 1921, of American nurses and social workers. These experienced women devoted themselves to supervising the nursing work of the clinics, to giving instruction in home visiting and social service to the native nurses, and in forming

committees of citizens cooperating in the work of the centers. In the larger cities, notably in Riga, child welfare work of a high order had been carried on before the war. During the past winter large amounts of clothing have been distributed to children throughout the three states. More than 40,000 children, selected by local committees, have been assisted in this manner, and various philanthropic agencies and institutions have been given generous allotments of garments.

In addition to this plan of rather general material and medical relief for the children of the Baltic States, early in the present year certain strategic centers were chosen in each country for setting up an intensive child health program, i. e., one which attempts to reach and keep well every child in a selected area. The expectation is that when work of this character has been carried on sufficiently long, the results obtained in the reduction of sickness and death among the child population, will be so striking that other similar centers will be started elsewhere. Every effort has been made to avoid expensive methods, and to stress simply the fact that the reaching, if possible, of every expectant mother and every infant while well, with the proper medicine, advice and nursing supervision, will demonstrate that children may be healthily born and reared even amid adverse surroundings. The following is the outline prepared for use in these demonstrations in child health which are now started in several centers of the Baltic States. We believe the methods are sound and if followed in any community will serve, perhaps, in the most convincing way, to show how easy it is to reduce mortality and morbidity among children.

### Outline of Work

The object was to reach all expectant mothers and all children in a given area, that is, children from 0 to 2 years, all children from 2 to 6 years, and to keep all these groups under supervision until the withdrawal of the American personnel, and thereafter through local nurses and doctors continuously. The slogan is "to keep well children well," and by simple but well proven methods, to lower mortality rates among children.

The preferable procedure in a city community should be (a) to choose a political unit for the ease of securing statistics, as a ward or

police district, with a fairly average population of 20,000 to 30,000 people; not necessarily the poorest and not where any one political or religious group predominates in a manner in any way calculated to embarrass the enterprise. (b) Wherever possible in connection with the unit, arrangements should be made for the registration of expectant mothers, for at this time the advice of a physician and nurse usually is most willingly received. This contact may in some cases be best made through an existing obstetrical clinic or a physician experienced in this field. (c) In several countries birth registration within a short period is available under the law. The statistical bureau of many cities can furnish once or twice a week a list of all the new born babies in the political unit, and therefore can give the present total infant death rate under one year existing in the district chosen. (d) Where no statistical bureau exists the approximate registration can often be made through churches, at the time of baptism in Lutheran and Catholic churches, and through the Rabbis among the Jewish populations, clinics, where there is an existing obstetrical or prenatal clinic, house to house canvass, or police registration in small communities. In some instances a whole town of 5,000 to 10,000 may well be chosen. Here there is less likelihood of securing accurate statistics. In both these instances, town and city communities, only places are selected where cooperation under American supervision is possible, and where there is a possibility of developing good committees to continue the demonstration. The essential features of this plan are applicable to purely rural communities.

The building selected for the center must be in or close to the political unit of the city in which the intensive work is planned; preferably in a pediatric clinic working in close affiliation with an obstetrical clinic. An unusually favorable place for this intensive program is in association with some strong pediatrician using his clinic as the local. The quarters for a three room center should contain a waiting room furnished with benches, one table and filing cabinet. The examination room should contain an examination table for babies, lever scales, small supply cabinet, wash stand and basin, table or desk, chair, microscope, slides and stains, and urine analysis set. There should be in the kitchen facilities for heating milk and facilities for cleaning bottles.

Where it is possible, the expense of equipment, light and heat and maintenance should be shared in, to a large extent, by the local societies.

In some instances it may be necessary to give milk and certain supplies. This, however, is not an important consideration of the clinic, and should only be done to help the individual child, and it is recommended that supplies should not be distributed from the center but from some other location, on order of personnel in the Center.

The phases of management as it relates to the infant: (a) Babies should be brought to the clinic once a week up to three months; from three months to seven months, twice a month; from seven months to one year, as often as the attending physician deems necessary. (b) When the new born baby is under the care of a private doctor, there should be one visit to the home, and the doctor asked to give a report once in two months on the condition of the baby. (c) In case of illness the center is responsible for the baby's care, and where this can not be provided in the home, adequate hospital supervision must be found. (d) When the baby is removed from the district, an effort should be made to keep in touch with it at regular intervals.

As it relates to the personnel, management should provide that (a) where the American Red Cross has medical, nursing or social welfare personnel, the A. R. C. officer in charge will inspect and report regularly on the operation of the activity. (b) A native doctor trained in pediatrics should be in charge of the center and should hold clinics as often as is necessary to comply with the above program. In beginning this intensive work, it would be advisable to have the whole time of a qualified native doctor. Provision should be made for home visits by the doctor when necessary. (c) The nursing activities are to be under the direction of the American Red Cross nursing service, even in the event that the entire nursing personnel are local nurses.

(d) The social worker will organize and cooperate with the local committees having in mind the permanency of the work, this committee to meet at regular intervals and advise as to the conduct of the work of the stations. The social worker will also give instruction in social service to nurses and volunteers. It may be advisable to have the social worker direct the business of the station, the filing of records, etc. In centers in which there may be no social worker, a socially trained nurse will take over the active functions. (e) Of

course, the chief object in making this demonstration in intensive child welfare work is that the usefulness of the work for children should so impress itself upon the community officials and physicians that they will be willing to carry on after the withdrawal of the American Red Cross, and also to reproduce similar centers elsewhere. The responsibility for this, however, is assumed by the head of the American Red Cross Commission. Personnel in the Centers are only responsible for the character of the work there performed.

Standard records are provided and should be carefully kept up to date. At each visit of the infant a notation should be made by the nurse or doctor as to the care demanded. The records are attached. Records of the mother and children belonging to the same family should be kept in a single folder so that each family group may be found together.

An important feature of a child health program is to care for children of runabout age, namely, from two to six years. One clinic a week for this group should be established at a specified hour and each child belonging to this group should report at least monthly. This is an age in which many serious physical defects develop; defects which are often easily remedied if recognized in their incipency. It may be wise in each center to have a separate clinic for older children—those of school age, or to cooperate actively with school physician in the chosen district in the care of this group.

In regard to the examination of patients, (a) expectant mothers should be examined as early as possible in their pregnancy. Examination should include the condition of the heart, urine, pelvic measurement and unusual findings. Examination of urine in normal cases should be repeated each month and oftener if there is an indication. Any abnormal condition found by the nurse in home visit upon expectant mother should be promptly reported to the physician.

(b) Examination of babies should include the weight, length, condition of the glandular system, heart and lungs, abdomen, nervous system, skin, bones and any unusual findings. (c) Examination of older children should include height, weight, throat, glandular system, eyes, heart, lungs, abdomen, nervous system, bones, skin and unusual findings.

Appointments should be made with mothers specifying the date and hour on which they should return to the center and they should be given a slip with the time of return written or stamped thereon and when they do not keep these appointments they should be visited in their homes. As the numbers grow, it would be desirable to make these appointments for various mothers at slightly different hours so that many will not be kept waiting at one time in the center, excepting, of course, on those days when instruction is given to a group of mothers. Following out this rule, much time will be saved to the patients.

It is essential that the survey of the area should be as complete as possible. This should include information about churches, schools, clinics and volunteer organizations in the area. Information also as to the general housing conditions, water and milk supply, drainage and similar factors affecting health should be obtained.

An enlarged map outlining the area should be made and put on the wall for ready reference.

It is extremely important and should be emphasized at all times that the clinic primarily should be considered as for the care of well children. "Keep well children well" is the idea that should be kept constantly in mind and should be explained to all of the agencies in the district and elsewhere as well as to the local physician to whom would be referred sick children. The health center physician might dispense simple remedies for very mild ailments and might give after investigation, to certain cases, both mothers and children, additional foodstuffs to increase their nourishment.

Work of the above character is now under way under the direction of Colonel Ryan, M.D., and under the immediate supervision of an American nurse and social worker, in Narva, Reval and Dorpat, in Esthonia; in Libau and Riga in Latvia, and in Kovno in Lithuania. We are particularly interested in these demonstrations in the university towns of Dorpat, Riga and Kovno, for here it will be possible to acquaint medical students at first hand with the comparatively simple

methods of keeping well children well, so that when these students enter into medical practice they will be interested in and know how to carry out similar work in their own communities.

In order to continue the child health program in the Baltic States after the withdrawal of the American personnel, the great need is for nurses who have had some public health training. This was appreciated early, and a well-trained nurse with qualities of leadership has been chosen from Esthonia and one from Latvia, and have been sent to London for a graduate course in public health nursing. In order better to equip other nurses in social nursing so that they can carry on our work and do public health nursing in their own countries, a short course in public health nursing has been opened in the celebrated university town of Dorpat. Only the more experienced nurses have been selected by the health department of each country. Lectures are given by the members of the medical faculty and by an American public health nurse, and the students receive practical training in the intensive child health center at Dorpat, which is administered from the university clinic. We feel that the twenty-five nurses who are taking this course, will be greatly helped by this experience in carrying on child health work in their respective countries. The expenses of all these nurses attending the course are being paid by the health departments and the national Red Cross societies.

We are asking the professors of pediatrics in the universities of Riga, Dorpat, and Kovno to be especially interested in our intensive centers, and on withdrawal to give them their personal supervision, and we have every assurance that the work begun as outlined will be continued permanently. Already more than twenty of the smaller clinics are being maintained entirely by local resources.

The American Red Cross Commission to Western Russia and the Baltic States has given itself unsparingly during a period of war and pestilence to the care of wounded soldiers and to the stamping out of a devastating epidemic. It has fed and clothed thousands of dependent civilians, women and children, and has provided for them medical and nursing care, and has planted the seed of thoroughgoing child health activity in the newly formed states which it is hoped will take root and multiply until unnecessary sickness and death may be done away with.

## Digest of Sanitary and Hygienic Advance

RESEARCH is ranging far afield in the endeavor to discover new and improved remedies for those diseases in which there exists in the blood-stream a living parasite, thus, Fournier, Leviditi, and Schwartz reported to the Biological Society of Paris at its June 24, 1922 meeting (*Gaz. d. Hôp.*, 1921, 51, 95, p. 828) the results of their experiments with the salts of vanadium in the treatment of experimental and human syphilis. They pointed out that the three elements, arsenic, antimony and bismuth, belonging to the same series in the Mendeleef classification, possess an energetic power against the *Spirillaceae*, the *Spirochaetacea* and the *Treponemata*. They were therefore led to perform experiments with the view of determining whether or not the various members of the sub-group of vanadium, niobium and tantalum possess any similar powers, particularly with regard to syphilis. No appreciable results were obtained with niobium and tantalum but vanadium proved to have a treponemoidal power approaching that of the salts of arsenic and bismuth. Tartrovanadanate of potassium injected subcutaneously into infected rabbits in doses of Gm.0.015 to Gm.0.020 per kilogram of weight brought about the disappearance of the treponema in from twenty-four to forty-eight hours and the cicatrization of the syphilitic lesions in three or four days. In human syphilis, tartrovanadanate in 2 per cent solution administered subcutaneously or intramuscularly in Gm. 0.10 to Gm.0.15 doses every two or three days gave the following results: disappearance of the treponemata after the first or second injection; cicatrization of the chancre and erosive syphilids of the skin and mucosa, sometimes very rapidly; and very marked reduction of the adenopathies. Observation over a considerable period of time of patients thus treated seems to show that vanadium not only clears up the surface lesions but also exercises a profound influence on the evolution of syphilis in such a manner as to warrant more exhaustive research for more potent and less toxic compounds.

### Intravenous Injection of Quinin

Brahmachari (*The Lancet*, 1922, cciii, 5160, p. 175) sounds a note of warning against the careless intravenous injection of quinin solutions and points out that there may be a

dangerous fall of blood pressure following the injection of concentrated solutions of the salts of quinin in the treatment of malaria. He concludes that in giving bihydrochlorid by this method, the solution should not be stronger than 1 to 300 and the rate of injection should never exceed 10 c.cm. per minute in patients over fifteen years of age. Below that age the maximum rate should never be above 5 c.cm. per minute.

### Novel Method of Lining Sanitary Drainage Ditches

Years ago at Panama, Gorgas treated drainage ditches by floating burning crude oil down them, thus not only killing vegetation and baking into a sort of earthenware the interior of the ditch but also actually lining the ditch with the unconsumed asphaltum deposited there. Many of these ditches still function perfectly. An improvement on this method is described by de Verteuil in a paper addressed to the Royal Society of Tropical Medicine and Hygiene and read at its meeting of June 2, 1922 (*The Lancet*, 1922, cciii, 5159, p. 131), dealing with the methods of Anopheles and malaria control put in force in the Brighton-La Brea Rural Sanitary District of Trinidad in 1920 and subsequent years. An unprecedented Anopheles invasion in 1920 led to the clearing of all grass for a radius of two hundred yards from about bungalows and building and the brushing, cleaning and drainage of all drains. It is not improbable that grass-cutting was valuable chiefly because it permitted the discovery and filling of small breeding places rather than that the grass itself was a breeding or harboring place for the Anopheles. Other breeding places were filled, drained, or treated with crude oil. Cleared drains were then burnt out with an oil mixture as in the Gorgas method. Later a mixture of liquid asphalt and sand was ignited and allowed to flow along the course of the open drains. When this cooled, there remained a smooth, impervious lining of asphalt and sand which resisted scouring by run-off and prevented the growth of vegetation in the ditch. The cost of lining surface drains by this method was fourteen to twenty cents per square yard, as compared with one dollar per square yard of concreting. In this connection it should be borne in mind that asphaltum is plentiful and cheap in Trinidad and that the

life of an asphaltum-lined ditch is probably not as great as one lined with concrete.

### Anthrax Hazard in Tanneries

That American hides and skins constitute a small anthrax hazard and that foreign hides and skins are a genuine danger is the belief of Smyth (*Am. Jour. of Hygiene*, 1922, ii, 4). It is his conviction that anthrax is a continuing menace to the workers in the receiving, soaking, and liming departments of the Pennsylvania tanneries and that all imported, non-packer hides and practically all goat skins should be considered as possible sources of infection. Anthrax has been isolated from certified hides and certified goat skins, and certified hides and goat skins have been responsible for human cases of anthrax. Dry hides have been responsible for more cases of anthrax than greensalted hides. The exclusion of imported hides would lessen the incidence of human anthrax. Imported hides and skins should be thoroughly disinfected at ports of entry by either the Schattenfroh or the Seymour-Jones method. As a means of lessening the risk of infection and with the purpose of diminishing the liability of the more or less permanent infestation of soak-vats and their surroundings in tanneries, whitewashing should be liberally and frequently employed for all exposed wood, concrete or metal work about store rooms, soak-rooms and in the beam house. Adequate wash fixtures and shower baths with hot and cold water, soap, and towels should be provided for the exposed men. Towels, overalls, and workshirts should be provided for the workmen by the tanner and laundered at his expense after thorough disinfection. Towels, clothing, and shoes should never be taken from the tannery until they have been properly disinfected. Dry sweeping should not be permitted in tannery stock and store rooms.

### Septic Sludge and Ankylostomiasis

That the use of septic tank effluents as manure is fraught with a certain amount of danger of infecting the soil with hookworm is evidenced by McVail's report (*Ind. Jour. Med. Res.*, 1922, xxi, 4, p. 806 *et seq.*) of the examination of 107 specimens of septic effluent taken from fifty-six dif-

ferent septic tanks. In nineteen of these effluents, living *Ankylostoma* eggs and larvae were found, while in fifteen samples, *Ascaris* eggs and in one those of tapeworm were observed. Most of the infected specimens were obtained from the tank direct but in one instance the effluent had passed through a trickling filter. Overworked tanks and those containing much sludge gave more larvae than those that were in good condition. Free chlorin apparently did not kill larvae.

#### Preservation of Rat Poison Baits

The addition of boric acid solution, 1 to 40 or carbolic acid solution one to forty to poison baits prevents their deterioration and apparently does not detract from their attractiveness for rodents.

#### Avicenna and Tuberculosis

There seems to be little doubt that many of the so-called modern medical beliefs are very ancient and that what we regard as recent discoveries were in reality known long, long ago. The report of Dinguizli of Tunis to the French Academy of Medicine (*Gaz. d. Hôp.*, 1922, xcv, No. 53, p. 859) on the beliefs of Avicenna (A.D. 980-1037) regarding tuberculosis, tends to bear this out. Considering his time, the conceptions of this Arabian physician and philosopher are remarkable. He believed in the contagiousness and curability of tuberculosis and recognized its spread by contact of the sick with the well. His pathological observations were no less original and ingenious than are his epidemiology. Avicenna studied the ulcerations of the mediastinum, the pleura, and the lungs, the effects of tuberculosis of the lungs and its extension to the pleura and vice versa and he considered these tuberculous ulcerations as perforating and non-perforating. He recognized three evolutionary stages in true pulmonary phthisis; (1) a pre-inflammatory stage with an ulcerous eruption; (2) a more advanced stage, with an attack upon the deeper tissues and the breaking down of the ulcer; (3) the ulceration progresses, presenting the appearance of a true fistula and cavity formation. Avicenna counsels direct action upon the ulcer by means of a fluid containing much honey or by means of an infusion of red roses. At the same time he praises the absorption by the gastric route of great quantities of honeyed or sugared red roses. He recommends the milk cure, the milk of the ass or goat being considered best when it can

be obtained uncontaminated. He also insists upon the cure by life in the open air and on the value of moral treatment.

#### Carbon Tetrachlorid Hookworm Treatment

Additional evidence of the superiority of carbon tetrachloride over thymol and chenopodium in the treatment of hookworm is furnished by the reports of the work of Hall in the Fiji Islands and Ceylon issued by the United States Department of Agriculture. Twelve thousand Fijis were successfully treated by this method without any ill effects.

#### The Diagnosis of Tuberculosis

Constantly, laboratory workers are seeking to perfect tests whereby the diagnosis of tuberculosis may be accurately made very early in the disease. Such labors will go far in assisting the clinician and will also be welcomed by the sanitarian since their application will afford additional means of removing the tuberculous from circulation and of returning a certain proportion of them to safe and useful lives. Landgraf (*Boitr. z. Elin. d. Tub.* 1, 1922) has experimented with the Wildholz urine test at the Communal Tuberculosis Hospital in Hanover and obtained positive reaction in ninety per cent of the open cases, in eighty per cent of the closed cases and in forty-four per cent of cases which were clinically doubtful. Those results depend upon the assumed presence of certain specific antigens in the urine of the actively tuberculous, the demonstration of which may be made by the inflammatory skin reaction subsequent upon the subcutaneous injection. There are no general or focal reactions and while extraordinary care and minute attention to the details of the technique are absolutely essential to success, Stubbe's reports (*Hospitalstidende*, Feb., Mar. '22) seem to indicate that the test promises to be useful both in a qualitative and quantitative way, since there seems to be a direct relation between the extent of the skin reaction and the extent and activity of the disease process.

The specific fixation of complement by Bosredka's antigen is another test whose reliability is being confirmed. This test, first demonstrated by Bordet and Gengou is performed with the extract of tubercle bacilli grown on egg culture medium. Ichok (*Par. Med.* xii, 1922, xxiii, 485) states that this is made by adding one liter of distilled water of neutral reaction to the

yellow of twenty eggs. An emulsion is made, clarified with sodium hydroxide, diluted to seven liters, placed in Roux boxes holding from 50 to 150 c.c., and sterilized at 110 degrees C. for twenty minutes. Sterile, fourday cultures form the antigen. In nine hundred persons tested by this method negative reactions were constant in the non-tuberculous. Kempner (*Deutsch. Med. Woch. Ber.*, Mar. 24, 1922, xlviii, 12), had positive reactions in 82 per cent of 131 clinical cases of tuberculosis and 3.5 per cent in fifty-seven persons supposed to be in good health. In the use of Panches complement fixation test, Punch and Gosse (*B. M. J.* 3211, July 15, 1922, p. 79) report that after two years experience with this method it is their opinion that the test is positive before tubercle bacilli can be demonstrated in sputum, that it was positive in 98 per cent of cases with tubercle bacilli in the sputum and the test was negative in 98.5 per cent of controls consisting of healthy persons or persons suffering from disease other than tuberculosis.

#### Hereditary Syphilis

Leredde (*Soc. d. Med. de Par.*, May 27, 1922, *Par. Med.* 1922, xii, 27, p. xii) states that according to data collected by him from the Statistical Office, hereditary syphilis including congenital debility and the like, kills at least forty thousand children in France yearly.

#### Bubonic Plague Treated with Neo-Salvarsan

In a letter appearing in the *British Medical Journal* (3212, July 22, 1922, p. 127) Ram Mansoor reports the successful treatment of a case of bubonic plague by the intravenous injection of Gm.0.45 of neosalvarsan. This method should be borne in mind in situations in which Yersin's serum is not available.

#### Hereditary Microcephalus

According to Berstein's very careful study (*Jour. of Hered.* 1921, xiii, 1, p. 31) microcephaly or "pin-headedness," occurs about twice as often in men as in women, a fact which has long been one of the basic beliefs of the feminist party. In the family which supplied the clinical material for this report, out of ten children, five males and five females, there were four male and one female microcephalic persons. One of the microcephalic males is dead. The remaining three are respectively 34, 32, and 28 years, while the female is 23 years

old. All have the mental age of three years. The three boys' heads measure 15, 15½, and 16 inches in circumference. The girl is cross-eyed and all the children have the faces and bodily slackness typical of their condition. There is nothing in the lineal or collateral history of this family to account for the occurrence of these microcephalic children and apparently the only family factor reflecting degeneracy is alcoholism on the part of the father.

CHART I.—PORTION OF THE GENELOGICAL TREE OF THE SO-CALLED PIN FAMILY

During 1921 there were 12,500 deaths—one every forty-two minutes, night and day—and over 300,000 other injuries from automobiles in the United States. It is reported that the number of automobile accidents is increasing each year while the number of traffic accidents is generally decreasing. The movement for the education of children in accident prevention is a good one but should be expanded. This is a field of genuine public health work which should receive the active support of health workers in general and of health officers in particular.

Fetal Welfare

Mellroy, in a letter to The British Medical Journal of July 22, 1922, urged that the British Medical Association take some definite action on the question of fetal welfare at the annual meeting at Glasgow. He states that at present there is a vast amount of ante-natal mortality which cannot be estimated by any other method than that of mere guess work. "Until obstetricians urge the necessity for the registration or notification of abortions, no reliable information can be obtained as to the enormous wastage of child life. . . . The registration of illegitimate births has not given rise to difficulties, and now that V.D. conditions are liable to notification surely no objection can be put in the way of any honest endeavor to combat the fetal mortality which is known to be so great. Notification of abortions might to a small extent curtail criminal methods of child murder which are so widespread." It is

his belief that a great number of the ante-natal and intra-natal deaths are easily preventable by the adequate training of students, midwives and post-graduates. Maternity hospitals should have an indoor and outdoor ante-natal or fetal welfare department, and facilities for the necessary bio-chemical and bacteriological investigations of ante-natal conditions. The life of the child should be cared for from the earliest conception of the ovum, and this attitude towards obstetrical problems will give results far beyond our present imagination, not only in ante-natal treatment but perhaps most of all in the prevention of intra-natal complications and operations.

The Cost of Dementia Praecox

Prof. G. M. Robertson in his presidential address before the Medico-Psychological Association of Great Britain at its annual meeting in Edinburgh on July 19 made the statement that "one mental disorder alone—namely, dementia praecox—probably costs the country more in maintaining its hopeless victims for life than any other single disease."

Antityphoid Vaccination in France

Dopter, in his annual review of the infectious diseases (*Par. Med.* xii, 22, June 3, 1922, p. 453) gives some very interesting data—particularly interesting to the sanitarian who recalls the extreme conservatism which the French exhibited to this valuable method of typhoid fever prophylaxis at the beginning of the war. He urges the need of the obligatory vaccination of those engaged in the care and nursing of persons suffering from typhoid fever and notes that of 1,739 nurses vaccinated at the Salpetriere since 1921, only one case of typhoid has been observed. The effect of the vaccination of the men called to the colors has been remarkable and in many parts of France it has been noted that the great bulk of cases has been in non-vaccinated women and in non-vaccinated boys not yet of military age. For example, at Havre there were 72 cases in 1921, of which 41 were males and 37 females. Of the males, 37 were less than twenty years of age and 4 had been mobilized during the war. Of these four, three had never been vaccinated and one only (a paratyphoid B by blood-culture) had received three injections. The author believes that so far as the civil population is concerned, it is

preferable to advance anti-typhoid vaccination by persuasion rather than by obligation, since the fear of the vaccination reactions amounts almost to a "phobia." It is necessary to provide many centers for free vaccination and this is being done throughout France. It is felt that the campaign of persuasion will make more rapid progress if some other route of introduction of the vaccine than the subcutaneous is developed. The results obtained with Besredka's entero-vaccines in the hands of Vailant and Nicolle seem to be encouraging. As another method of solution Lumiere and Chevrotier (*Comp. rend. des Seances de l'Acad. des Sciences*, clxxiv, 16, April 18, 1922, p. 1080) set forth a method of anti-typhoid vaccination by scarification. They have demonstrated that guinea pigs vaccinated by twelve scarifications are resistant to the injection of massive doses of virulent cultures of the typhoid bacillus as well as paratyphoid A and B. The scarifications are not accompanied by any particular reaction other than that which may follow an insignificant skin traumatism. The method is reported to be efficacious and to be particularly applicable in cases of cardiac or renal disease or any other condition which would contra-indicate the employment of the sub-cutaneous route or the use of entero-vaccines.

Practical Means of Controlling Botulism

The heat-resisting spores of the bacillus botulinus, according to the California State Board of Health (*Weekly Bul.* 1, 19, June 24, 1922) are found practically everywhere. When they are sealed in a can or jar of food material which was not properly sterilized at the time of canning, the absence of air and the presence of food favors the growth of these organisms and a toxin of highly potency and extreme concentration is formed. It is recommended that all home-canned vegetables and meats be boiled for at least thirty minutes before tasting or eating, since even the least taste of this toxin may result in death. In home canning, the use of a steam pressure cooker will reduce losses from spoilage and protect the lives of subsequent consumers.

At the annual convention of the Baltimore and Ohio Association of Railroad Surgeons in Chicago a campaign to educate railroad employees regarding the danger of contagious and social diseases was initiated.

## The Upbuilding of the Public Health Profession

IN AN address delivered by John R. Freeman, President of the American Society of Civil Engineers, last June, occurs the following striking phrase. "The special mission of Science—the organization of knowledge, the discovery of natural law, and its expression in formulas—has been to bring safety and economy into the constructive arts."

Public health is one of the most vitally important of the constructive arts, but its development toward "safety and economy" falls far short of that attained by the arts of the engineer. There are two fundamental reasons why this must be the case. In the first place, public health deals with problems, biological and social, vastly more complex than those involved in the strength of materials or the flow of water through pipes, so that it is more difficult for the health officer than for the city engineer to define exactly the procedure which should be followed in a given case. In the second place when the engineer knows what ought to be done he has only to convince a small group of executives and his task is complete; while the health officer must not only convince the intelligence but alter the daily habits of the in-

dividual citizen if his objectives are to be attained.

The public health worker has therefore confronted a difficult and twofold task, the improvement of standards of practice in his profession and the mobilization of effective popular support. During the fifty years' life of the American Public Health Association this organization has held both these objectives more or less in view although in its early days the first was clearly dominant. A serious study of the situation, precipitated by vigorous discontent expressed at the New York meeting a year ago, led at Cleveland last month to a clarification of aims which promises to prove of capital importance. It has been decided that the improvement and standardization of health department practice and its protection against ignorance from within and political pressure from without is the primary task of this Association. In the words of the Committee on Reorganization, "The objectives of the Association should be the preparation, study, standardization and presentation of scientific public health procedures, and the best methods by which such knowledge can be given to the public and the expression to the public of professional opinion in regard to such procedures." The Report of the Committee on Municipal Health Department

Practice presented at Cleveland, reviewing the work of the eighty-three large city health departments of the country, and presenting standards for an ideal health department in a city of one hundred thousand population, is an example of the type of work to which the Association plans to devote itself in the future. In justice to the past, it must be remembered that earlier efforts of the Association along this line in standardizing procedures for the laboratory examination of water, milk, and air, for the control of steam pollution, and the disposal of municipal wastes, and for the isolation and quarantine of communicable diseases, have for years exerted an influence upon American health practice which is responsible for some of its most substantial achievements.

The Association will be enormously strengthened for work of this type by the changes made in its constitution and by-laws at the Cleveland meeting. While anyone interested in public health can be admitted as an associate member and anyone actively engaged in public health work as a member, the power to vote and to hold office in the Association is now limited to fellows, who must be professional health workers of established standing and who must serve two years as members before being eligible for election to fellowship. The technical sections of the Association (Public Health Administration, Laboratory, Vital Statistics, Sanitary Engineering, Food and Drugs, Industrial Hygiene, Child Hygiene, Public Health Nursing and Health Education and Publicity—the last two at present provisional sections) are given a larger direct share in the government of the Association; and it is provided that state societies affiliated with the American Public Health Association shall be accepted only when organized like the parent body primarily along professional lines.

The American Public Health Association, while thus devoting itself to perfecting public health practice, has not discarded the work of organizing popular support for the public health movement without making sure that this important task was somehow provided for. Experience has shown that such popular support, as manifested for example in the state tuberculosis associations, is far more effective if primarily a voluntary community movement, working with, but not dominated by, state and local officials. The A.P.H.A. has therefore turned to the National Health Council as representing not only the National Tuberculosis Association but the leading voluntary health agencies in general and asked for its aid; and the National Health Council at Cleveland adopted the following highly significant resolution:

That the Council undertake the definite and aggressive promotion of State Health Councils to be patterned after the National Health Council in those states where the member agencies and their local representative agree that this form of organization is the next step in a logical development toward health coordination.

This means that the National Health Council and its constituent members will go forward with the task of mobilizing popular support for the public health program, while the American Public Health Association is left free for its own proper work, the development of the constructive art of public health to the highest practicable degree of safety and economy. The very existence of a distinct profession of public health is often unrecognized by municipal officers who control the demand for sanitarians and by medical students whose choice of a career limits the supply. If the plans conceived at Cleveland are carried through to their logical conclusion the words "Fellow, A.P.H.A." will have a significance that will attract the able young men so greatly needed in this field and will ensure them the public recognition that alone can make their work productive.

---

### Trends in Public Health Nursing

**B**OTH the Report of the Committee on Nursing Education appointed by the Rockefeller Foundation and the Report on Municipal Health Department Practice of the American Public Health Association, in discussing the organization of public health nursing favor the combination of bedside care with health instruction in a generalized district service; and in so doing they represent the obvious tendencies of the best public health nursing practice throughout the country. It has become abundantly clear that the work of a purely instructive nurse, valuable as it may be, is relatively ineffective when compared with that of a nurse who has rendered direct aid in time of need, particularly if through a generalized service she has touched the life of the family repeatedly and at many points. On every hand we hear of the change from a specialized to a generalized plan and of the combination of bedside and instructive service—almost never of changes in the opposite direction.

There is probably today sufficient evidence at hand to warrant voluntary public health nursing organization in shaping their policies, as rapidly and as far as circumstances may permit, toward a generalized district service. The future policy of the municipal nursing service is much less clear. Shall it continue to maintain a purely instructive specialized service in parallel with the work of the voluntary District Nursing Association as is the case in most cities today? Shall it abandon public health nursing to private agen-

cies? The first course is to some extent wasteful and inefficient—the second unthinkable. There remain still two other possibilities—the taking over of the whole work by the municipality—or the working out of a cooperative plan like that in force at Dayton, Ohio, by which municipal nurses and privately employed nurses are pooled in a common generalized service. The assumption of entire responsibility for all types of public health nursing, including the care of the sick on a visiting nurse basis, seems the logical outcome for the ultimate future and is recommended by the A. P. H. A. Committee for its ideal health department. Such a course, however, contravenes the principle held sacred in Massachusetts and in many other communities of the absolute separation of preventive work from the care of the sick and opens up the difficult question whether patients who are able to pay for nursing care should be given such care by the state without charge (as they are given education today); or, if not, whether it is possible for the city to offer a service free to the indigent and for cost to those able to pay. Furthermore in any given case it would be most unwise to transfer public health nursing from an efficient private organization to a municipal department, not prepared to administer it with approximately equal effectiveness. We shall need much patience and much open-mindedness and much unselfishness in order to find the right solution of these problems and the solution must temporarily at least be materially affected by local conditions in each community.

---

---

### A Health Convention Month

**O**CTOBER was a busy month for the public health worker, with four different conventions in two different cities demanding his attention; and we have felt compelled to devote a large proportion of this issue of *THE NATION'S HEALTH* to condensed first-hand reports of these meetings.

The Social Hygiene conference at Cleveland indicated normal and encouraging progress of the great movement for the hygiene of sex life. The Fifty-first Annual Meeting of the American Public Health Association at Cleveland was marked by a fundamental step forward in the reorganization of the Association along definitely professional lines, discussed more fully in our leading editorial. The American Red Cross convention at Washington was of interest from the standpoint of the public health worker for the stand made by Judge Payne and others against the attempt of reactionary elements to eliminate the constructive peace-time activities of the Red Cross and to re-

duce it to the pre-war basis from which Mr. Henry P. Davison built it into a great organization. It is probably too late now for the American Red Cross to carry out a broadly constructive campaign of public health education such as Mr. Davison conceived and such as the Red Cross societies of certain other countries have adopted with success; but we may at least hope from Judge Payne's pronouncement that the splendid service of the A. R. C. in the field of public health nursing will not be allowed to suffer any check.

The meeting of the American Child Hygiene Association in Washington was notable among the conventions of the month, for one event of far-reaching importance. The Child Hygiene Association and the Child Health Organization of America have agreed to combine their forces into a single great organization which shall deal with all the problems which relate to the health of the child from prenatal life to adolescence. The workers for child health have again set an example in cooperation to us all as they did when they established the Child Health Council which led to the formation of the National Health Council. The new Child Hygiene Association, among its many opportunities for service, is charged with the administration of the generous gifts of the Commonwealth Fund for the establishment of child health demonstrations in three communities; and the results of these experiments with the similar tuberculosis demonstration to be conducted by the Milbank Foundation should exert a compelling influence on the development of public health practice in the future.

### The Care of Tuberculosis in Industry

**T**HE MT. MCGREGOR Sanatorium maintained by the Metropolitan Life Insurance Company for the care of its tuberculous employees has recently published statistics which indicate that of a group of patients discharged for an average period of three and a half years, 75 per cent were living and at work. This is a splendid and inspiring result. It is due, as in other similar cases, solely to one factor—the prompt beginning of treatment. At Mt. McGregor as elsewhere cases admitted in the incipient stage show admirable results (84 per cent living and at work) and cases admitted when the disease was far advanced show poor results (20 per cent living and at work). The secret lies in the fact that of 953 patients, 585 were admitted in the incipient stage, 333 in a moderately advanced stage and but 35 in a far advanced stage. Early treatment is made possible by regular annual physical examinations, by free sanatorium treatment, by a plan of sick-

ness insurance and by the fact that the patient who completes treatment is sure of returning to his job.

Such a system could scarcely be put in force by an industrial concern less financially strong and less socially minded than the Metropolitan. For the community as a whole, however, there is a significant lesson here. The community cannot, in the long run, escape the financial burden of tuberculosis. Will it not be more economical to work out a community plan for securing early treatment that will be 75 per cent efficient than to blunder along as at present with an efficiency of only 25 per cent?

---

### The Progress of the Social Hygiene Movement

IT HAS been pointed out that the great work of the late Prince Morrow lay in the fact that he took a number of different tendencies—medical, moral, educational, and social—and united them in the single stream of influence which we call the social hygiene movement. Today there is a tendency, and a sound tendency, to carry out certain distinct phases of the campaign for sex hygiene through the activity of district agencies. Health departments should be primarily responsible for the direct control of venereal disease. The eradication of commercialized vice and the beneficent protective work which has developed so rapidly since the war should be centered in the local police departments and in the Department of Justice at Washington. The fundamental tasks of education in sex hygiene must be accomplished in our schools. Furthermore it seems clear that the activities of the specialist in mental hygiene will play a more and more important part in the campaign as time goes on and will perhaps constitute a fourth and more or less distinct phase of the movement as a whole.

A number of distinct agencies cooperating on a community plan for a common end is the essential for success. That some degree of success is already in sight would seem clear from the report coming in from venereal disease clinics all over the country of the relative decrease in early cases submitting themselves for treatment. We want of course to get every new case in the earliest possible stage; but when the proportion of early cases diminishes in face of a vigorous campaign for prompt treatment the facts suggest a real diminution in new infections. From England, where the social hygiene movement is in many ways as far advanced as our own, comes the news of significant decreases in the death rates from *tuberculosis dorsalis*, general paralysis, and aneurysm while the

death rate from syphilis has remained stationary in spite of a great increase in the birth rate which, since syphilis as a cause of death is so largely infantile, would have naturally increased the crude death rate from this cause. The reduction in combined death rate from these four causes taken together between 1915 and 1920 amounts to 31 deaths per million population, a gain of substantial significance. Even in France there are signs of a new attitude toward the social problems of sex hygiene which should bear substantial fruit. It is a time for the health officer and the social reformer and the teacher and the mental hygienist to take up the fight with renewed courage for the enemy is in retreat.

---

### Common Sense in Sewage Treatment

THE little city of Lima, Ohio, has become a battleground upon which the attention of sanitary engineers from all over the country is just now focused. The State Department of Health ordered the treatment of the sewage of this city in order to prevent a nuisance created by its discharge into the Ottawa River. Plans for a trickling filter plant were prepared under competent advice and approved by the state authorities. At the last moment the city fathers were persuaded to submit alternative plans for treatment by the so-called "Direct Oxidation" method which plans now await the judgment of the State Department of Health.

It appears to be admitted that while the new method proposed will cost about two hundred thousand dollars less for construction it will cost over forty thousand dollars a year more for operation, involving an enormously increased burden upon the municipality. It is claimed that the effluent from the "Direct Oxidation" process will be better than that from the trickling filter which is theoretically possible although the fact that the "Direct Oxidation" process will require exceedingly careful operation and is untried in large scale practice (except at Allentown, Pa., where conditions are quite abnormal) makes it doubtful whether theoretical conditions will be realized.

The fundamental question, however, is one of engineering economics. There is urgent need for funds to carry on all sorts of really important and fruitful lines of public health activity. It seems therefore inexcusable to spend money for carrying sewage treatment to a point of refinement not called for by local conditions, and the opinion of the consulting engineers who recommended the trickling process and of the state department which approved it should be sufficient to indicate that the lesser degree of purification

involved will meet the needs of the Lima situation. We have often seen a high degree of purification forced on a community by state authorities; but it is unusual to find a city requesting from such authorities permission to spend its own money on ultra-refinements.

Furthermore, even where a high degree of purity is required the "Direct Oxidation" process appears from all present knowledge to constitute an unduly expensive method of obtaining the results. It is essentially a method of excess lime precipitation combined with electrolytic treatment. Excess lime precipitation has been used for many years and it is mainly upon the oxidation and sterilization effected by electrolysis that the "Direct Oxidation" process depends for its alleged value. It is an attempt to capitalize the mysterious efficacy which everything electrical exerts upon the lay mind, but the plain fact is that the production of oxidation by direct electrolytic action in sewage is a costly and relatively inefficient procedure. When the "Direct Oxidation" plant at Allentown gets into normal operation so that the Pennsylvania State Department of Health can study it we shall know more definitely what this process can and cannot do. Meanwhile municipal authorities would do well to cling to well established methods and to remember the old dictum that "an engineer is a man who can do for one dollar what any fool can do for two."

### Sir Thomas Browne and His Skull

IN the editorial section of the April issue, THE NATION'S HEALTH noted with that satisfaction which was universal among medical litteratti, the family reunion which recently took place between the skull of Sir Thomas Browne and the other remnants of his anatomy. It now appears on no less authority than the Reverend Canon F. J. Meyrick,<sup>1</sup> that there is a doubt as to the authenticity of the skull which is now interred in the chancel of St. Peter's Mancroft, Norwich, England, beneath Bishop Pollock's beautiful inscription

*O caput augustum, Petro custode sepulchri  
Sit tibe par; nomen vivat in urbe; vale.*

The developments of recent investigations with regard to this skull are interesting in the extreme, particularly to those who appreciate the quaint philosophy of the author of the *Religio Medici*. In 1840, according to Meyrick, (the present vicar of the church where Browne was buried in 1682) a local antiquary with a highly developed "acquisitive complex," taking advantage of the opening of the chancel for a fresh interment, pur-

loined the heraldic escutcheon from Browne's leaden coffin. This was the coffin plate which bore the oft-quoted Latin inscription:

*Hoc locule indormiens corporis spagyrici pulverere plumbum in aurum convertit.*<sup>2</sup>

Although denying the theft of this plate, which was returned to the church fifty-three years later by his executors, the antiquarian claimed that the lead of Browne's coffin had decomposed and that through the opening thus formed, he saw the skull and the "profuse and perfect," fine auburn hair of the occupant. In 1845, a skull purported to be that of Sir Thomas Browne was presented to the Norfolk and Norwich Hospital, where it was kept until recently in a silver casket presented by Sir William Osler, our own beloved authority on Browniana. A few months ago the Hospital authorities returned this skull to the church from which it was supposed to have come.

Whether this skull was originally "acquired" by the antiquary who claimed to have seen it, or whether it was stolen by the sexton, a man whose reputation was above such an act, or whether it is a bogus skull palmed off on the hospital authorities as that of Sir Thomas, is not known. Neither is it recorded how Dr. Lubbeck, who made the original gift to the hospital, secured possession of it.

Meyrick doubts the authenticity of the long auburn tresses, some of which accompanied the skull to the hospital, because Brown was seventy-seven years of age when he died, but suggests that perhaps he was buried in his wig. After comparing the skull with fourth authentic portraits showing Browne with the noble, intellectual forehead of a scholar, he doubts if the low, receding, depressed forehead of the returned skull could ever have housed the great philosopher's brain, but he suggests that possibly the artists who made the paintings may have idealized their subject's brow.

But, after all, what difference does it make? It was the contents of Sir Thomas Browne's skull and not its boney casket which produced the *Pseudoxia Epidemica*, Urn Burial, and Vulgar Errors and which thereby made an impress for all time on philosophic medicine. The words of this great thinker have inspired many men and are as immortal as the songs of Homer. But what a pathetic irony there is in the wanderings of the skull of him who said

"To be knaved out of our graves, to have our skulls made drinking bowls and our bones turned into pipes . . . are tragical abominations escaped by burning burials."

2. Sleeping in this grave, by the dust of his alchemic body he changes the lead to gold.

1. Brit. Med. Jour., May 6, 1922, vol. 3201, p. 725.

## Industrial Hygiene Section of A. P. H. A.

**A**N INTERESTING situation in Ohio was brought out in the remarks of Dr. Wade Wright, chairman of the Industrial Hygiene Section of the American Public Health Association at Cleveland, October 18-19, in regard to the collection of data regarding industrial dispensaries. The Department of Health has asked the Ohio Association of Industrial Physicians to appoint a committee to work jointly with them, both in developing suitable forms for the collection of information and for so tabulating the results as to make the records of the greatest value both to the Health Department and to physicians in industry.

Dr. S. S. McCurdy argued for such improvements in differential diagnosis of occupational diseases as will make it possible to eliminate specific industrial factors in lowered resistance. Heart disease, for instance, he thinks will show a reduced rate when such cases are segregated and placed in occupations which will nurse the handicap instead of increasing it. Dental dispensaries have shown their value. Whole-time eye surgeons likewise will come and, properly employed, will prove to be a real economy.

An interesting analysis was made by Dr. Charles A. Swan of the causes of absenteeism among store workers. His statistics covered a period of six months, including both winter and summer months of absenteeism among 1,500 store employees. Diseases of the upper respiratory tract predominated. Women were absent two and one-half times as much as men and married women 58 per cent more than single women. The employees of the store were rated according to physical examination into three classes: (A)

those showing no physical defects; (B) those showing minor defects; (C) those handicapped to a degree that affected their vocational placement. In class B the absence rate was 12 per cent higher than in class A and in class C 42 per cent higher than in class A. In practically every case employees showing a physical defect even in minor degree were more susceptible to disorders of various kinds.

The discussion brought out the fact that absenteeism among executives has not received the attention it deserves. Here the adjustment of the load requires the highest skill of medical profession. In all groups psychic factors have much to do with absenteeism; it is notable that large percentages of affected employees get well over Monday, fewer on Tuesday and almost no recoveries are recorded on Saturday. It was brought out in the discussion that a very small percentage of industrial physicians are doing real research work in the plants.

A very valuable survey of the compensation aspects of industrial eye injuries was given by Dr. William Mehl of Buffalo. The difficulty of rendering absolute justice in matters of this kind is evidenced by the confusion among ophthalmologists themselves who have never been able to agree upon a satisfactory percentage ratio of visual loss. Certain states fix the standard of industrial blindness but the rating of partial losses is in confusion. Dr. Mehl himself offered the following table:

20	25	61%
20	30	121½%
20	40	25%
20	80	75%
20	100	100%

The discussion brought out particularly the discrepancies of the Ohio law governing compensation in visual injury. There is no compensation in Ohio for permanent loss for less than 50 per cent of vision. The difficulties encountered are further increased by the fact that all impairment is estimated on the basis of full correction, whether the victim can stand the full correction or not and regardless of whether he can work with them or whether he is financially able to fit himself with glasses.

The practical application of mental hygiene in industry was discussed by Dr. Frederick W. Dershimer. The mental causes of inefficiency are many and may be removed by the simplest measures of physical adjustment of working conditions or may require methods of psychoanalysis. It is particularly important in cases of injury to discover the first examination whether the individual is affected by anger or fright. In every case the disability is exaggerated by a grudge or a latent motive for revenge; it is not too much to charge the industrial physician with the necessity of helping the patient to effect a compromise of such complexes and nervousness. The physician who fails to practise mental hygiene fails to live up to his opportunities. Mental hygiene is properly the concern of industrial medicine.

Dr. H. J. Howk described the remarkable results obtained in the treatment of tuberculous employees of the Metropolitan Life Insurance Company at Mt. McGregor Sanatorium. Of 953 cases discharged since 1914 it was found December 31, 1921, that 75 per cent were at work, 10 per cent living but not working, 10 per cent

dead, and 5 per cent had been lost track of. The number of cases and percentages of cases at work classified according to their condition on discharge are shown in the accompanying table:

CLASSIFICATION OF TUBERCULOUS EMPLOYEES OF METROPOLITAN LIFE INSURANCE COMPANY DISCHARGED FROM MT. MCGREGOR SANATORIUM.

	Moderately Advanced	Incipient	Far Advanced	Total
Number of cases.....	333	585	35	953
Percentage at work.....	66		20	75

The results are primarily due to the systematic annual examination of all employees, to the fact that treatment

is free, and a sickness insurance plan is in force, and to the further fact that the employee is assured of re-employment on recovery.

Dr. H. N. Cole presented a comprehensive discussion of industrial

dermatoses and analyzed their direct causes, parasitic, mechanical, chemical, and physical, and their contribu-

tory causes such as heat, posture, and individual idiosyncrasy. The importance of thorough washing and change of clothing was stressed and special reference was made to the frequency of dermatosis among nurses due to individual susceptibility toward certain of the drugs which their duties require that they must handle.

The final afternoon session was devoted to addresses and demonstrations on school, home, and industrial lighting by M. Luckiesh and Ward Harrison of the Neal Research Laboratories in which the meetings were held.

## A Teaching Device for Fatigue Elimination\*

BY FRANK B. GILBRETH, LL.D., CHAIRMAN, COMMITTEE ON ELIMINATION OF FATIGUE IN INDUSTRY, SOCIETY OF INDUSTRIAL ENGINEERS, MONTCLAIR, N. J.

AS A fatigue committee of the Society of Industrial Engineers our work must progress along two lines. First, we must increasingly cooperate with others engaged in other types of work to prevent duplication of effort and gain speedily a body of cooperators who have the same general interests at heart. Second, we must develop units, methods, and devices that will be useful in the elimination of unnecessary fatigue.

The presentation of a new and simple teaching device specially designed to eliminate fatigue in the transference of skill or in studying the one best way to do work is especially timely due to the emphasis at the joint management meeting on the transference of skill. That the merits of the methods used by different workmen vary greatly is well known. Few managers, however, realize the extent of variation. In searching for the one best way to do work, we have not yet found any two workers who do their work in exactly the same way. In thirty-seven years of motion study we have never found a method of any worker that could not be improved upon by substituting in part the method of some other worker. We have never found a method synthesized from the best worker obtainable that could not be improved by the leisurely examination of micromotion records of such methods. It is by no means rare to find that the man with the best motions can perform his work in one-third of the average time of his fellow worker. The man with the quickest method often has also

the least fatiguing method of work.

The inferior methods of many journeymen are handed down through generations of apprentices who little realize their resulting handicap and who study and try to imitate whatever is taught them regardless of its efficiency while the few pupils of the most expert do not necessarily have the opportunity to acquire the special skill or the super-skill of the expert. It is less than four hundred generations of apprentices back to the cave man, less than two hundred to the stone age, less than a score of generations to many journeymen who could not read and write, and less than one generation to the recording of the one best way and the precious skill of the super-expert.

The device, called the "Magster," for short, signifying magazine filled with stereographs, is an inexpensive stereoscopic viewer of magazine rolls of moving picture photographs on paper of time and motions. Its cost is trivial. It permits all investigators and learners alike to see the super-expert's methods in infinite detail in a leisurely manner; it permits maximum transference of skill from the super-expert without personal contact, it permits interchange of demonstrations of skill from all parts of the world without the presence of the super-skilled demonstrator. No longer is there any more excuse for the misled apprentice and learner and the perpetration of inferior designs of tools, unnecessary-fatigue-causing-work places, and inefficient methods of work than there is excuse for perpetrating inferior strains of horses, cows, sheep, pigs, and hens.

The demonstrations of the one best teacher are as useable after he passes away as when he lives at his best. Such a viewer permits the slowing down of motions made at the speed of practise to that of still pictures. It presents to the learner not merely moving pictures but consecutive snapshots showing the elements of causes of skill. Fast motions and slow motions are not alike as to relative speed, relative positive, and negative acceleration, path, direction, muscle rebound, or automaticity. This device permits the capture of complete details of methods and also the errorless times of their elements in three dimensions by means of a stereoscopic cinematograph, and permits also the viewing of the permanent printed picture on paper with a wide angle stereoscope showing a dozen or more pictures for comparison at the same time without winding the paper record. Alongside each picture is the reason and the proof of the features contained therein showing its excellence. The symbols of the blings, or elements of motions, illustrated by the records may be entered on the margin and the learner stimulated by questions. This also insures suggestions for improvements and adaptation to each individual learner for greatest output and with least fatigue, for even the method of the best man obtainable is not perfect. It also allows a chance for extended discussion during the demonstration.

The Magster is sufficient and complete for the recording of the elements of motions and for the making or comparing of simultaneous motion charts. Other devices made from the

\*Read at meeting of the Society of Industrial Engineers, New York City, October 15, 1922.

original micromotion negative, from which the paper prints were made, permit viewing the records as stereoscopic moving pictures either on paper or on film. The device is usable by those who have not the super-experts to demonstrate, or apparatus available, or the micromotion technical experience or knowledge to capture and record in complete detail the best way to do work. The Magster is to the super-expert demonstrator of the one best way to do work what the graphophone is to Kreisler or Caruso. It puts the long years of research, development and practice of micromotion study within the reach of the non-technical foreman and worker, the apprentice, and the beginner. As a result, the Magster now makes it no more necessary for the one who

wishes to see the one best way to do work demonstrated to make the record, than it is necessary to make a graphophone record in order to use such a record.

This device is offered to the engineering and teaching professions, but first of all to the fatigue committee, without patents, with the hope that each community, school, and library will have records of the super-skill of the best demonstrator obtainable regardless of where he may be and regardless of whether he is living at the time that his super-skill is examined and imitated. Thus, it is now possible to present to the apprentices and workers of the world, the chance to see the methods of the best workers available, in their chosen life work, which is a step toward their ac-

quiring first habits and automaticity in method of the best way to do their work.

Knowledge of the one best way to do work disseminated throughout the world will help reduce the gigantic preventable waste which has been evaluated by this society and by Mr. Williams, engineer of the National Safety Council, as averaging more than twenty cents a day for each worker in the United States. The members of this society and the knowledge and the apparatus are ready to superstandardize the one best way in all trades. It will be interesting to note how long it takes for the country to overcome its mental inertia and to discard its present ridiculous customs and traditions of teaching its people their life works.

## Great Britain's Place in Fatigue Elimination\*

BY HENRY J. SPOONER, C.E., M.I.MECH.E., F.G.S., MEMBER OF THE INTERNATIONAL COMMITTEE ON INDUSTRIAL FATIGUE, LONDON, ENGLAND.

THE scientific study of the laws governing the healthy employment of the human mind and body in industry was strangely late in its development in Great Britain, although it was in this country that the industrial revolution had its first beginnings, and industrial development was most rapid, and also that geographical, social, and political conditions combined to intensify the evils arising from the neglect of scientific study. Even in the long parliamentary battles fought during the nineteenth century upon the specific question of the reduction of the daily hours of work, battles fought between the advocate of a *laissez faire* policy followed in the supposed interests of production and national wealth on the one hand, and those pressing the claims of human charity upon the other, no appeal was made by either side to the laws of physiology or to the test of experiment which might very rapidly have shown that a reduction of hours would have increased industrial output no less than human happiness and health.

It was not until 1893 that Messrs. Mather and Platt of Manchester conducted their well-known pioneer experiment on this subject. Mr. Mather (later, Sir William Mather), to whose initiative this work was due, primarily endeavored to show that "work before breakfast" was open to economic as well as social objections. The

working day during the two years' experimental period, was accordingly shortened permitting work to begin at 8 a. m. instead of 6 a. m., and the breakfast interval was abolished. The experiment showed that the reduction in hours from 54 to 48 hours a week caused an increase in production and a decrease in lost time.

The results of this work were brought to the notice of the government in 1894, which upon the basis of the Manchester experiment, introduced the 48-hour week at Government arsenals and shipyards. The results gained by Messrs. Mather and Platt did not, however, lead to any general adoption by engineering or other firms of the analogous methods or to any organized study of the subject by the Government or private firms.

The first steps in the direction of a systematic study of industrial fatigue in Great Britain were taken in 1913 when the Home Office accepted an offer by Dr. A. F. Stanley Kent, Professor of Physiology at Bristol University, to undertake a series of experiments on behalf of the department in connection with industrial fatigue, especially the determination of suitable physiological tests for the measurement of fatigue,<sup>1</sup> subject to a financial contribution being made by the Home Office towards the cost of

providing apparatus. In the same year the British Association at its annual meeting appointed a research committee for the purpose of investigating fatigue from the economic standpoint.

The Great War brought into being the health of munition workers' committee under the Ministry of Munitions. The distinguished and influential committee under the chairmanship of Sir George Newman, K.C.B., M.D., F.R.C.P. was appointed in September, 1915, by the Right Hon. David Lloyd George, M.P.

The committee was invited "to consider and advise on questions of industrial fatigue, hours of labor, and matters affecting the personal health and physical efficiency of workers in munitions factories and workshops. The committee immediately commenced to energize and arranged to sit and take evidence not only in London but also in Birmingham, Sheffield, Newcastle, Glasgow, Manchester and Coventry. Special arrangements were also made for taking evidence at Woolwich, and witnesses were heard representative of employers, workers, factory inspectors, and other interested persons.

Having regard to the urgency of many of the problems involved by their terms of reference, the committee decided that it was desirable that they should submit their views and recommendations in regard to particular matters in separate memoranda rather than that they should defer

\*Read before the American Society of Industrial Engineers at the New York Meeting October 18, 1922.

<sup>1</sup>Interim Report on an Investigation of Industrial Fatigue by Physiological Methods, 1915 (Cd 8056). Price 5d. Second Interim Report on an Investigation of Industrial Fatigue by Physiological Methods, 1916 (8335). Price 1s. 6d.

making any report until their investigations were completed. In accordance with this decision, the committee submitted to the Ministry the following twenty-one memoranda, which were in due course published and placed on sale. The prices given are net and do not include postage.

### Official Memoranda

- No. 1. Sunday labor (Cd. 8132), 1d.
- No. 2. Welfare supervision (Cd. 8151), 1d.
- No. 3. Industrial canteens (Cd. 8133), 1d.
- No. 4. Employment of women (Cd. 8185), 1<sup>1</sup>/<sub>2</sub>d.
- No. 5. Hours of work (Cd. 8186), 1<sup>1</sup>/<sub>2</sub>d.
- No. 6. Canteen construction and equipment. (Appendix to No. 3), (Cd. 8199), 4d.
- No. 7. Industrial fatigue and its causes (Cd. 8213), 1<sup>1</sup>/<sub>2</sub>d.
- No. 8. Special industrial diseases (Cd. 8214), 1d.
- No. 9. Ventilation and lighting of munition factories and corksops (Cd. 8215), 1<sup>1</sup>/<sub>2</sub>d.
- No. 10. Sickness and injury (Cd. 8216), 1<sup>1</sup>/<sub>2</sub>d.
- No. 11. Investigation of worker's food and suggestions as to dietary (Second appendix to No. 3), (Cd. 8370), 1<sup>1</sup>/<sub>2</sub>d.
- No. 12. Statistical information concerning output in relation to hours of work (Cd. 8344), 1<sup>1</sup>/<sub>2</sub>d.
- No. 13. Juvenile employment (Cd. 8362), 1d.
- No. 14. Washing facilities and baths (Cd. 8387), 1<sup>1</sup>/<sub>2</sub>d.
- No. 15. The effect of industrial conditions upon eyesight (Cd. 8409), 1d.
- No. 16. Medical certificates for munition workers (Cd. 8522), 1d.
- No. 17. Health and welfare of munition workers outside the factory (not published).
- No. 18. Further statistical information concerning output in relation to hours of work with special reference to the influence of Sunday labor (Cd. 8628), 1917-18, 3d.
- No. 19. Investigations of workers' food and suggestions as to dietary (Second appendix to No. 3). Revised edition (Cd. 8798). Session 1917-18, 2d.
- No. 20. Weekly hours of employment (Supplementary) (2d. to memorandum No. 5). Cd. 8801. Session 1917-18, 1d.
- No. 21. Investigations of the factors concerned in the causation of industrial accidents. (Cd. 9046). Session 1918, 6d.

An interim report, entitled "Industrial efficiency and fatigue," was also published (Cd. 8511), (1s. 3d) in February, 1917, in which was set out the results of a number of investigations which had been made by the committee. The studies included were: (a) Industrial fatigue and its causes (reprint of memorandum No. 7); (b) output in relation to hours of work (reprint of memorandum No. 12); (c) the comparative efficiencies of day-work and night-work; (d) the causes and conditions of lost time; (e) incentives to work, with special reference to wages; (f) report on the health and physical conditions of male munition workers; (g) inquiry into the health of women engaged in munition factories.

In 1918, the committee published its final report entitled "industrial health and efficiency" (Cd. 9065). This blue book of 180 pages reviews in a most useful and readable way the whole of the committee's activities from September, 1915, to the end of 1917, when the committee was disbanded. These pioneer researches into the effects of long hours of work upon output, upon accident incident, and upon sickness and lost time in munition

factories—which were necessarily limited to the war conditions of industry, and to the making of munitions—were productive of results sufficiently striking in themselves, but still more so in their potential application to industries generally.

On the disbandment of the health of munition workers' committee at the end of 1917 the Medical Research Committee and the Department of Scientific and Industrial Research, with the active encouragement of the Home Office, decided to form a committee to investigate the subject of industrial fatigue on more comprehensive lines by embracing all classes of factories within its scope. A research board was accordingly appointed in July, 1918, by the Medical Research Committee, now the Medical Research Council, and the Department of Scientific and Industrial Research jointly with the following terms of reference: To consider and investigate the relations of the hours of labor and of other conditions of employment, including methods of work, to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers; to suggest problems for investigation, and to advise upon schemes of research referred to them from time to time by the Medical Research Council, undertaken to promote better knowledge of the relations of hours of labor, and of other conditions of employment, including methods of work, to functions of the human body, having regard both to the preservation of health among the workers and to industrial efficiency; and to advise the council upon the best means for securing the fullest applications of the results of this research work to the needs of industry.

The present board consists of the following distinguished members: William Graham, L.L.B., M.P., and Member of the Medical Research Council, chairman; R. R. Bannatyne, C.B., Assistant Secretary, Home Office; C. J. Bond, C.M.G., F.R.C.S.; W. L. Hichens, chairman, Messrs. Cammell, Laird and Co., Limited; Sir Joseph Petavel, K.B.E., D.Sc., F.R.S., Director of the National Physical Laboratory; Sir Charles Sherrington, G.B.E., Sc.D., P.R.S., Professor of Physiology, University of Oxford, who acted as chairman of the board at its inception, but resigned the position on becoming president of the Royal Society; E. H. Starling, C.M.G., F.R.S., professor of physiology, University of London; Mona Wilson, J.P.; D. R. Wilson, H. M. Inspector of Factories, Secretary.

To secure adequate scientific supervision of research and criticism of the board's work, the Medical Council formed the following four special scientific committees: (1) Committee on industrial health statistics, chairman, Major Greenwood, M.R.C.P., Medical Officer of the Ministry of Health; (2) Committee on the physiology of muscular work, chairman, E. H. Starling, C.M.G., F.R.S., Professor of Physiology, University of London; (3) Committee on physiology of the respiratory and the cardiovascular systems, chairman, Leonard Hill, M.B., F.R.S., Director of Applied Physiology, National Institute for Medical Research; (4) Committee of Psychology, chairman, Henry Head, M.D., F.R.S., member of the Medical Research Council.

The following reports have been issued from 1919 to August, 1922, and can be purchased from H. M., Stationery Office, Imperial House, Kingsway, London, W.C.2. (the net prices given do not include postage).

- No. 1. The influence of hours of work and of ventilation on output in tinplate manufacture, by H. M. Vernon, M.D., (1919; price 6d).
  - No. 2. The output of women workers in relation to hours of work in shell-making, by Ethel E. Osborne, M.Sc. (price 6d; out of print).
  - No. 3. A study of improved methods in an iron foundry, by C. S. Myers, M.D., Sc.D., F.R.S., 1919 (price 2d).
  - No. 4. The incidence of industrial accidents upon individuals, with special reference to multiple accidents, by Major Greenwood and Hilda M. Woods; 1919 (price 6d).
  - No. 5. Efficiency and fatigue in the iron and steel industry, by H. M. Vernon, M.D., 1920 (price 3/—).
  - No. 6. The speed of adaptation to altered hours of work, by H. M. Vernon, M.D., 1920 (price 1/—).
  - No. 7. Individual differences on output in the cotton industry, by S. Wyatt, M.Sc., 1920 (price 6d).
  - No. 8. Observations on bobbin-winding, by S. Wyatt, M.Sc., and H. C. Weston, 1920, (price 1s. 6d).
  - No. 9. A study of output in silk weaving during winter months, by P. M. Elton, M.Sc. 1920 (price 2s. 6d).
  - No. 10. Preliminary notes on the boot and shoe industry, by J. Loveday, B.A., and S. H. Muro (price 1/6d).
  - No. 11. Preliminary notes on atmosphere conditions in boot and shoe factories, by W. D. Hamby, B.Sc., and T. Bedford, 1921 (price 3/—).
  - No. 12. Vocational guidance, by B. Muscio, M.A., 1921 (1/—).
  - No. 13. A statistical study of labor turnover in munition and other factories, by G. M. Broughton, M.A., E. M. Newbold, M.A., and E. C. Allen, 1921 (price 3/—).
  - No. 14. Time and motion study, by E. Farmer, M.A., 1922 (2/—).
  - No. 15. Motion study in metal polishing, by E. Farmer, M.A., assisted by R. S. Brooke, M.A. (price 2/—).
  - No. 16. Three studies in vocational selection: A. The psycho-physiological capacities of hand compositors, by B. Muscio, M.A., B., The measurement of strength (with reference to vocational selection), by B. Muscio, M.A., C., Physical measurements in a confectionery factory, by E. Farmer, M.A., 1922 (price 1s. 6d).
  - No. 17. An analysis of the individual differences in the output of silk-weavers, 1922 (price 1s. 6d).
  - No. 18. Two investigations in potters' shop, 1922 (2s. 6d).
- First annual report of the Industrial Fatigue Research Board to 31st March, 1920 (price 6d). This report gives an account of the origin of the board, the methods of research employed, and the investigations undertaken.
- Second annual report of the Industrial Fatigue Research Board, to 30th September, 1921

(price 1s. 6d.). The most valuable feature of this report is an analysis of the published work of the board, consisting of the above 18 reports.

As is well-known, in 1920-1921, the Government of Great Britain was faced with the stupendous problem of balancing the nation's finances, with unprecedented unemployment and the burdensome, crushing income-tax of six shillings in the pound, and drastic economies had to be resorted to with the object of reducing the taxation that was and is strangling industrial life and enterprise. So, at the end of January, 1921, the Industrial Fatigue Research Board received a provisional notice from the Medical Research Council that the Treasury, having regard to the financial condition of the country, and to the prevalence of unemployment and short-time employment, could not contemplate the continuation, after March 31 of the financial provision which had previously been made for the work of the board, and that they requested that steps should be taken by that date to transfer any important work in hand to the independent support of industrial or other voluntary associations. This proposal which the Board had had no previous reason to expect, appeared to them likely to have most unfortunate results, and they felt it to be their duty to make the strongest representations to the Council against the abrupt termination of any parts of their work without inquiry into their value to industrial health and economy, or, again, into the practical possibilities of voluntary support being forthcoming from industries or elsewhere at short notice at that time. The Board is glad to recognize that the steps which have been taken by the council to insure the continuance of its work has not only enabled it to avoid the sacrifice of many data already collected, but will permit it to undertake fresh investigations, though on a more restricted scale than previously.

In the concluding paragraphs of the board's last published annual report (the second, to September, 1921), the board's views as to the cooperation of the industries with the board are given as follows: As the work of the board proceeds, however, new fields of investigation are continually opening out, which lie beyond both the scope and present resources of the board. If these are to be adequately explored, the board thinks it essential that the industries should expend their cooperation with the board, by agreeing themselves to assume partial responsibility for the super-

vision and financial support of the industrial side of the work.

The board is unwilling at the present stage to formulate any detailed schemes dealing with the method and extent of cooperation. They suggest, however, that for the successful development of the work on the industrial side due regard must be had to the following considerations: First, the board is disposed to think that industries themselves should have a full and even predominant share in the supervision of such investigations, and in deciding upon the problems to be studied. As already stated, the board is concerned primarily with the acquisition of scientific knowledge; in the practical application of such knowledge, industries are the best judges of their own needs. Secondly, the board regards it as important that responsibility for initiation and prosecution of the work should be shared, so far as possible, equally between employer's and workmen's representatives acting together.

Lastly, the board feels that, in general distinction from technical and material industrial research, problems arising in its work have often a common interest to more than one particular industry, so that economy as well as greater opportunities might be secured by adopting a wider unit of grouping, and by cooperation with groups of industries having certain features in common rather than with each such industry separately.

The ever-growing importance of time and motion study introduced and developed by the Gilbreths, was happily recognized by the board from the commencement of the investigations, as will be seen from the following extract from the first annual report:

The results of the inquiry into the methods adopted at the Derwent Foundry Company, an account of which is given in report No. 3, appeared to the board to be so significant that it resolved to start an investigation, having for its object the experimental introduction of motion study methods into an industrial establishment, combined with a careful measurement of the results. For such a result, the first step necessary was obviously to secure the goodwill of some employer, and after some unsuccessful attempts the board was fortunate enough to obtain the permission of Messrs. James Pascall and Sons, Ltd., confectionery manufacturers of London, to make use of their two factories for the purpose. In April, 1919, Mr. Eric Farmer, M. A., was appointed to take charge of the investigation, and Mr. C. Carlile has recently joined him as assistant investigator.

The processes selected for experiment are "dipping" (i.e., dipping almonds into melted sugar), and "bot-

ting," both of which are manual and depend entirely upon human effort. A long time must necessarily elapse before the success of the method can be definitely gauged, but from a preliminary report submitted in October, 1919, it appears that satisfactory progress is being made, and that even at this early stage increase of output has resulted.

Motion study is closely allied to vocational selection, and an investigation bearing on the latter has recently been carried out by Mr. Farmer; measurements of the hands and fingers of over one thousand girls have been taken with the object of finding whether dexterity in a given process is due to any special characteristics.

A report by Mr. Farmer summarizing this work (No. 14) and containing a complete bibliography was duly published. In addition, research on this subject has been undertaken by Mr. Farmer, assisted by Mr. A. S. Brooke, M.C., M.A., and Mr. C. Carlile, B.A., in the factory referred to above, and in the Sheffield Flatware Company, Ltd., cutlery manufacturers, and the results have been published. (Report No. 15.)

In reply to an inquiry as to what reports the Industrial Fatigue Research Board have in preparation, the Secretary of the Board, D. R. Wilson, Esq., H.M. Inspector of Factories, wrote that several reports were in course of preparation by his board which would be published in due course. One of these deals with certain factors in accident causation, two of them with atmospheric conditions in certain textile processes, and the fourth with values of efficiency in cotton weaving.

It is explained in the second annual report of the board that the following received financial support from the board during the year 1921: Research on effects of work on pulse variations and wink reflex (conducted by Dr. B. A. McSwiney, M.B., and Mr. W. D. Hamley, M.Sc.); research on respiratory metabolism (conducted by Dr. A. D. Waller and Miss G. de Decker); research on estimation of respiratory quotient in women (conducted by Professor Winifred Cullis, D.Sc.).

As has been pointed out a large amount of important work in fatigue elimination covering a wide range of researches has been carried out by the government of Great Britain; and in a general way the authorities concerned are fully alive to the economic and humanitarian importance of the work; but its ever-increasing range naturally tends to limit what can be done in the investigation of any particular aspect of fatigue, no matter how important it may be. This must

surely be the reason why so little has been done in any country to subdue those noises which have been carelessly allowed to accompany the advances of civilization,—noises that cause immeasurable pains and discomforts, and represent in their ultimate effects the loss of undreamt-of millions of money. For noise, particularly when accompanied by vibrations imparted to the body, is most harmful to the human machine by its corroding and decaying effect on the nervous system. We are told by Sir Robert Hatfield that what the world loses through rust and decay of ferrous metals amount to about £500,000,000 a year, how much greater must the loss be due to disease and

waste of life caused by harmful noise! The campaign against avoidable noise has been rapidly growing, however. Industrialists in increasing numbers are considering their own particular problems, and experiments have recently been made on the rolling stock of the London tubes with the object of reducing the deafening, nerve-racking roar, rattle, and vibration of the carriages that make conversation impossible and rob us of our energy and strength. As to the street trams that run on rails with grinding clamor, their further extension in any civilized country should be damned from the standpoint of harmful noise and vibration alone, and the sooner they are scrapped and replaced by rubber-

shod dirigible vehicles the better for suffering humanity. Not a little of the noise of vehicles running on rails is due to corrugation of the rails which is apparently caused by the moving load generating stresses on the surface of the rails in excess of the elastic limit of the material, and the prevention of this is a puzzling problem.

In conclusion, I venture to submit that there is no aspect of fatigue elimination that so loudly calls for the attention of any government as noise; and that in its reduction or elimination—and in the solution of allied problems—there is the widest scope for exercising the genius of physicists and scientific engineers.

## Finding and Caring for the Tuberculous Employee\*

### Industry Should Not Only Discover Disease But Should Give Treatment

By JAMES A. BRITTON, B.S., M.D., MEDICAL DIRECTOR, INTERNATIONAL HARVESTER COMPANY, CHICAGO, ILL.

ABOUT fifteen years ago an agitation was begun to control the spread of tuberculosis among employees of industrial establishments. It was said on so-called good authority that pulmonary tuberculosis was largely due to occupation, and that while the number of cases was not known in any industry, it was felt that the number was large and steadily increasing. From this agitation many special investigations were started by social organizations, labor unions, insurance companies, and by the management of large industries. Previous to this time, except for employment in certain branches of railroad service and such municipal departments as that of fire and police, a routine physical examination of applicants for employment in civil occupations was unknown.

The special investigations undertaken showed that there was to be found among those working in almost every industrial group cases of open active pulmonary tuberculosis. The finding of those cases of tuberculosis gave rise to the same two questions that always occur in relation to the discovery of a case of any infections or contagious disease,—(1) what shall be done with those already inflicted, and (2) what shall be done to prevent others becoming infected?

The next few years saw the estab-

lishment all over the country of sanatoria built or subsidized by private organizations, labor organizations, insurance societies, and industrial groups. During the same period in order to prevent the admission of new cases of active tuberculosis to industrial groups, the practice of making physical examinations of all applicants for employment was recommended and established in a great many places. With the establishment of a physical examination for all new employees, one of the constant sources of new cases of tuberculosis was largely eliminated; the problem, however, of discovering the cases of tuberculosis which developed among those already employed was not so easy. To one who has not had experience in dealing with the various problems which arise between employer and employee, it might seem that this difficulty could be easily handled by simply arranging for periodic physical examinations of all these employed. There has been so much publicity and argument on the subject of periodic physical examinations for every one that there is no necessity for discussing the advantages of this plan here. It is conceivable that in certain communities or in certain groups a plan of periodic physical examination for every one could be worked out so as to be mutually beneficial and satisfactory. But under existing conditions, I firmly believe that such a plan can-

not be established except in a partial and incomplete way.

For example, it is a simple matter for one of the large industrial concerns to say to its employees that we will provide a physical examination for every employee and if anyone is found who has tuberculosis we will provide sufficient funds to guarantee adequate sanitarium care until such time as he is able to resume his work and will guarantee him employment when this time comes. A large industry employing five, ten, or fifty thousand employees could make this sort of a proposition without piling up an item of expense which would be more than a very small percentage of its payroll. We must remember, however, that for every large industry having five thousand or more employees, there are really hundreds of small establishments having less than one hundred employees and such an establishment would find the expense incident to the care of a single case of tuberculosis a very large percentage of its payroll; in fact so large as to make consideration of such a plan prohibitive.

Any method of supervising those already employed, which means throwing out on the community those who are unable to work, will never solve the problem. On the other hand, any plan of supervising the health of any group of employees must carry with it some plan of adequate care of those found suffering

\*Written for the annual meeting of the National Tuberculosis Association, Washington, D. C., May 5, 1922.

from disease. It is granted that it is possible to adopt and carry out almost any health conservation plan in any industry providing the industry is large enough. The same thing is not true of the individual small industry, but it would be true if, instead of the individual small industries attempting to operate a health plan of its own, there were a sufficient number of small industries which were willing to pool their health interests. While there are a number of large concerns in which health conservation plans have been established which provide for periodic inspections or examinations of employees and study and correction of all unhealthful conditions or places, in the great majority of industries this work falls far short of the ideal, and is generally incomplete and unsatisfactory.

In any large industry certain jobs are found to have a considerable higher rate than that for the entire industry. Fortunately these jobs are few. Likewise certain industries are found to have higher rates than the average. Unfortunately, there are occupations where cases of tuberculosis can be definitely tied up to the job as a causal factor. This is particularly true in certain types of grinding which use the old fashioned large wet grindstone, produces a fine, sharp, cutting dust which causes gradual and permanent changes in the lungs, making a condition particularly favorable to the development of the lung infection. Incidentally, the prognosis for the arrest of the disease which has developed in this type of case is very poor.

#### Drink Cause Eliminated

One of the complicated industrial causes of tuberculosis was associated with drinking; a few years ago it was customary to permit employees of steel mills, foundries, forge shops, and employees of other hot or dusty jobs not only to drink as much liquor as they wished outside of the job, but to carry liquor into the workshop. The combination of a hot job and too much liquor resulted in disturbances in digestion which undermined resistance and made conditions right for the development of tuberculosis.

The care of the tuberculous employee is no different from the care of any other tuberculous member of the community. While it is possible to get as good results by treating a patient in his own home as it is in some sanatorium, it has been my experience that an arrest of the disease sufficient to warrant returning

to work can be obtained in much less time and in a much higher percentage of cases if the patients have a few months' sanatorium care than if they are treated at home. In my opinion, then, it is of the utmost importance if any industry wishes to do aggressive, effective work in the rehabilitation of its tuberculous employees to provide for sanatorium care.

While I believe that tuberculosis like any other communicable disease is in a large measure a community problem and that care of cases of tuberculosis should be provided for in public institutions at the expense of the general community, the handicaps under which even the best public sanatoria labor at the present time make it rather difficult to persuade the average employee of an industrial concern to accept care at one of these public institutions unless he is very ill. Because the average well run private sanatorium does not have to contend with the same handicaps as most public institutions, the service to the individual patient is usually more satisfactory and the period of treatment much shorter.

The so-called industrial tuberculosis work was begun in some instances as a special piece of health work. The original propaganda leading up to this work emphasized the importance of special plans for discovery of cases, special personnel, and special provision for treatment of cases. It is impossible in industrial work to pick out one special phase of medical work and emphasize it without consideration of other diseases and other medical problems. While, for example, heart disease has not had anything like the special consideration by industrial physicians as has been given to tuberculosis, there is reason to believe from the standpoint of number of cases and economic loss that heart disease among industrial employees is a greater problem even than that of tuberculosis. In my opinion, the plan for the discovery of cases of pulmonary tuberculosis among employees should be only a part of some comprehensive health supervision scheme. The only thing that stands in the way of developing a routine periodic thorough physical examination is the necessity for some comprehensive plan for taking care of those physical handicaps discovered when such examinations are made.

Shop conditions, and by this is meant both the sanitary conditions of the working place and the hazards of the job, are in most industries being rapidly and systematically checked and unsatisfactory conditions are be-

ing eliminated or corrected. This is the usual thing found in the modern progressive industry. The modern industrial physician's office not only keeps track of every accidental injury, and how, when, and where it occurred, but the same system of records is maintained for every case of illness developing among the employees. In the same manner as they point to defective machines of the lack of safety appliances, such records point out the unsanitary work room and the dangerous job.

In order to do a satisfactory job in finding and caring for the tuberculous employee, it is necessary to have a plan, an equipment, and a personnel which can give not only satisfactory service to the case of tuberculosis, but can also give this same service to an employee regardless of whether he has this disease, or disease of the kidney, heart, or nervous system, or any other disease which might interfere with or stop his work.

#### Early Discovery Essential

There are a great many problems which have come up in the field of industrial medicine which have caused considerable divergence of opinion regarding the limits of this field. There can be no difference of opinion, however, regarding some of the basic essentials. Both for the sake of the employee and the industry in which he is employed, it is necessary that his tuberculosis as well as his other diseases be discovered when there is some chance of arrest or cure. In order to do this, it is essential that the medical personnel in an industrial establishment be made up of well trained physicians, surgeons, technicians, and nurses. The day is past when the "first aid boy" will serve the purpose. In addition, the industrial physician's office must be equipped for thorough and accurate work.

The industrial physician who serves the community best, will not have much to do with the treatment of individual cases. He must be trained and equipped to recognize conditions and causes and do this fairly accurately. Recognition of tuberculosis must be a part of his job, not all of it. While he will not treat many cases, he must know what is good treatment and where it can be had and the procedure necessary to get it.

Any comprehensive plan must include a satisfactory plan for treatment. Simply finding and excluding those having disease from employment will not solve the problem.

# Industrial Morbidity and Accident Records\*

**D**ILIGENT inquiry among a large number of progressive firms having medical departments reveals the fact that there is as yet no comprehensive and coordinated effort in record keeping among such departments. The Committee, therefore, undertook to formulate a logical grouping of the different items which it feels must be considered in an intelligent analysis of morbidity and accident data. The suggested items serve as the minimum amount of information necessary for a useful analysis and are not to be considered as all that is desirable for this work. Individual plants can add to these minimum data such additional information as they desire.

The question of diagnosis is one upon which the Committee hesitates to make recommendations. At the present time there are two sources of information for diagnostic purposes, one, the International List of Causes of Sickness and Death, the other, Standard Nomenclature of Diseases and Pathological Conditions, Injuries and Poisonings, published by the United States Census Bureau. As they stand, both of these classifications are too bulky for industrial work. It may be advisable and necessary to develop diagnosis classifications by industrial groups as well as by disease groups.

Items under group (4), economic items, are necessary to tie the matter

physician, drug and hospital expense refers to the services of specialists and hospitals outside the industrial organization. The end result of the case, that is whether the employee died, returned to work or resigned, is also of importance.

Information desired in the Accident Records chart under items in group (1) is the same as that for medical records. In group (2) the item mechanical or non-mechanical attempts properly to place the responsibility either upon management or upon the worker. Under mechanical causes would be those due to lack of proper safeguards or other remediable conditions for which management is largely responsible; while under non-mechanical causes would be listed those for which the employee was primarily responsible.

The items in group (3) can be extended to any degree the individual plant may desire. All information called for is pertinent to the consideration of compensation claims and probably is already available in plants situated in states operating under workmen's compensation laws.

The items under group (4) are similar to those for the same group under medical records, although in this case, for compensation purposes, the amount of time lost refers to calendar time rather than to production time, as is the case in the medical records. The other items have been explained in the discussion of the medical section.

A practical obstacle in the accumulation of useful morbidity statistics in the past few years has been the high rate of labor turnover, and, more recently, the high rate of transfer from one occupation to another and from one department to another in the process of reducing personnel. In most industrial establishments, this latter process seems to be about complete. One cycle of industrial activity and depression has apparently terminated, but a new one has begun. Now that the number of employees in establishments is less, the work involved in record keeping is lessened and the data are more valuable because the worker stays long enough at one plant to permit observation of what actually happens from a health point of view. The present time is, therefore, opportune for inaugurating the collection of sickness data, even if the present industrial situation necessitates a very modest beginning.

MEDICAL RECORDS	
(1) Personal Items (employment data)	Name and address Shop number Age Sex Nationality Marital condition
(2) Plant Items (occupation data)	Department Occupation Previous occupations
(3) Scientific Items	Physical examination classification Diagnosis
(4) Economic Items	Amount of production time lost Amount of wages lost Cost of doctor, drugs and hospital expense End result

The items included under groups (1) and (2) of the Medical Records chart are already available in the employment records of most industries. Group 3 items are necessary properly to identify the case. These can be expanded as much as required and many include, in addition to diagnosis, methods and details of treatment.

Physical examination classification is important when available. The classification of physical findings adopted by the Conference Board of Physicians in Industry is recommended, as this scheme, or modifications thereof, is already in use in a large number of plants. This classification is as follows: Class I, physically fit for any employment; Class II, physically underdeveloped or with some slight anatomical defect; otherwise fit for any work; Class III, fit only for certain employment when specifically approved and supervised by the medical department; Class IV, unfit for any employment, rejected.

\*Report of committee on Standardization of Records for Medical Service in Industry submitted by F. L. Rector to the American Association of Industrial Physicians and Surgeons.

into the industry. The Committee feels at this time that the economic approach to this work offers the most favorable chances for its adoption with some degree of uniformity by industry. Industry is not interested in record keeping for purely statistical purposes, neither are the vast majority of physicians statisticians. However, the committee feels that if the value of this work from the economic standpoint can be shown to industrial management, the gradual addition of items of purely statistical interest will be an easy matter.

To determine the amount lost in production, time and wages would require the cooperation of the time-keeping and pay master's departments. To be of the most value the amount of time lost should be tabulated from a definite limit which involves the shortest practicable waiting period. It will doubtless be difficult to obtain an accurate record of illness entailing a time loss of less than the day or shift during which the illness began. The committee recommends that this basis be used for computing the time lost due to both illness and accident. The cost of

The Committee feels that until some such scheme record keeping as here presented is adopted and carried out by a representative group of industries for a sufficient length of time to enable a fair valuation to be placed upon this work, industrial medical work as a whole will not be able to make a proper showing in comparison with other departments of

building up of a definite record keeping program. The Committee recommends that some such coordinated effort be made by a group of interested plants. It is believed that there are already available disinterested organizations capable of making an analysis of such records.

If the science of preventive medicine in the industrial field is to pro-

The ideal way, of course, is for the foreign body to be removed at once that no bad results have been seen from allowing the foreign body to remain *in situ*, nor do the men complain of pain, Dr. Van Kirk reports.

In such case, the ophthalmologist must remove not only the foreign body but also all stained or devitalized corneal tissue. Unless this is done, the eye remains irritated for some days and is more liable to ulceration. The patch is then worn for twenty-four hours more at the end of which time usually no other treat-

ACCIDENT RECORDS	
(1) Personal Items (employment data)	Name and address Shop number Age Sex Race Social condition

the industrial organization. If a group of plants representing different types of industry would cooperate in keeping of such records for a definite length of time, say a year, and would then permit these records to be analyzed by some competent central body, information could be obtained which would form a basis for the

progress, its statistics must develop. No science can be expected to make much headway without a means of measurement. It would seem that there is not merely a field, but an urgent necessity for cooperative effort in the direction that will afford a real basis for the control and prevention of disease among industrial employees.

## Industrial Ophthalmology

**S**AFETY devices, education, expert ophthalmological attention are necessary adequately to protect the eyes of workers in chipping and grinding trades and in industries where there is possibility of molten metal endangering the eyes. Dr. V. E. Van Kirk of Pittsburgh presents in the *Journal of the American Medical Association* a study of twenty-five thousand cases from a steel mill employing about 8,000 men. The mill consists of furnaces, open hearth and Bessemer, rolling mills, and coordinating departments.

Safety devices result in a great saving of eyesight in industry and a saving as well in compensation to the employer. In one year alone in this mill twenty-five men were saved vision in one or both eyes and the employers saved \$50,000 to \$60,000 in compensation. Goggles should be worn especially by men engaged in chipping and

grinding, by men using the oxyacetylene torch or electric arc in welding, by furnace workers, and by others exposed to intense light. Men pouring babbitt metal should be provided with masks.

By far the greater part of industrial ophthalmology deals with the treatment of minor injuries of which the majority are foreign body cases. The attempt by a nurse or general practitioner to remove a foreign body from the eye is often attended with serious consequences. The procedure followed with success in this particular mill is, when the foreign body cannot be removed with a cotton swab, to instill into the patient's eye phenacain (holocain) or butyn solution, apply mercuric chlorid ointment, and a patch. The man is then allowed to return to some work safe and suitable for one wearing a patch and is seen at the next visit of the ophthalmologist.

This mask saved both eyes of the workman in an explosion of babbitt metal.

ment is needed. Trachoma must likewise be watched for.

The next step to be taken in industrial ophthalmology, Dr. Van Kirk states, is the refraction under cycloplegia of all employees and furnishing them with the proper correction.

Stimulated by significant findings of the English Departmental Committee Appointed to Enquire into the Ventilation of Factories and Workshops, the writers have carried on an exhaustive study on the relative value of lateral ports and inclined branch ducts, on uniform and tapered main ducts using both plenum and exhaust. They grade the efficiency of various combination, ranked in descending order and judged by evenness of distribution, as (1) plenum untapered with branch ducts, (2) exhaust untapered with branch ducts, (3) plenum tapered with branch ducts, (4) exhaust tapered with branch ducts, (5) plenum untapered with lateral ports, (6) exhaust untapered with lateral ports, (7) plenum tapered with lateral ports, and (8) exhaust tapered with lateral ports.

# The Functions of Medicine in Industry\*

BY JOHN A. LAPP, DIRECTOR DEPARTMENT OF SOCIAL ACTION, NATIONAL CATHOLIC WELFARE COUNCIL, CHICAGO, ILL.

THE natural state of man is in the open. His most natural employment is agriculture, hunting, and fishing. In an outdoor environment his health is promoted and he is protected against many dangers. This most natural condition of man's employment is, however, not the prevailing one in this country. Man has been taken out of his natural environment and has been placed in factories, mills, and mines; he has had placed in his hands strange tools with which to work, and is engaged in the operation oftentimes of complicated machinery. He is subjected not only to the ordinary burdens of work which he would have outdoors, but in addition he works at monotonous employment, often in unnatural positions, surrounded by foul atmosphere, sometimes by dangerous poisons. He is surrounded sometimes by unhealthy dust and by deleterious substances, acids, or poisons; he works in unnatural heat, in insanitary surroundings, under artificial light; he runs the constant risk of serious accident; he is fatigued by his unnatural employment and becomes for that reason a special prey of accident and disease. Clearly, the purpose of those who control industry should be to make the environment as nearly natural as may be possible.

We cannot go back to pastoral employments. Men under modern conditions must under present conditions work in factories, mills, and mines. The only way in which man's estate can be improved is to adjust the working environment to the men and women who work in industry, and to adjust the workers themselves, so far as possible, to the conditions of the new employment.

It should be perfectly clear to every one that industry exists for man, and not man for industry. The first consideration everywhere must be the human factor. Mere industrial success and money making cannot justify the physical destruction or deterioration of a single man. Industrial medicine should concern itself with the place of employment. One of its prime duties is to insure that the workers have a fit place to work, with due reference to the physical weaknesses which are inherent in mankind. Industrial medicine should determine

the sanitary conditions under which men work; it should see that all the environment protects the worker against the spread of disease and against conditions which may weaken the morale of the workers. Industrial medicine should look closely to the problem of ventilation, whether in office or shop. It should establish standards of lighting, so that the individual may be protected against the loss of efficiency, and perhaps even the ability to work through the deterioration of eyesight caused by bad lighting conditions. Industrial medicine must solve the problem of injurious dusts, gases, and acids. It is reported by good authority that in ordinary times more than four million men are employed in industries where injurious dust alone damages the health of the workers. Industrial medicine must study the problem of heat particularly in all industries where heat processes are a factor in production. Industrial medicine must consider the whole question of monotonous employment, fatigue, and posture required of workers at work.

## Protection of Children

On the other hand, the worker himself comes in for the study of industrial medicine. Some workers should be excluded from attempting to do certain kinds of work which may be dangerous to their physical well being. Children need particularly to have the unaccustomed burdens of industry properly adjusted to their backs. Women in industry present additional problems, requiring more careful adjustment in industrial work than others. Workers must also be protected against contagion, which may be disseminated by their fellow workers. All of this requires, in the first place, physical examinations. Around this subject of physical examination has revolved much controversy, but such controversies are due to lack of understanding of the purpose of physical examinations, on the one hand, and to unfair use of physical examinations, on the other.

Physical examinations may be for two main purposes: (1) to exclude workers from an employment; and (2) to adjust workers to the jobs which they can do best, and which will not be injurious to them. It is necessary in some employments to

have a physical examination for purpose of exclusion. Tests for color blindness are essential for signal men; candidates must necessarily be excluded if color blindness is found. Restaurant workers should be examined for communicable diseases, and must be rigidly excluded if found to be affected. Elevator operators should be excluded when a bad heart condition is found. These are samples of the proper use of exclusion as the end of physical examination. In many instances, which might be cited, exclusion is essential for the protection of the worker himself, his fellow employees, and the general public. The prime purpose of physical examination is to adjust the worker to positions which it will be safe for him to fill, both for himself and others, and which will enable the worker to develop the greatest amount of efficiency. Scientifically carried out, such examinations would find a proper and safe working place for men with physical or mental handicaps. Physical examination for this purpose is altogether too rare. Perhaps it is rare because of the high qualifications needed in the ones who make physical examination and the occupational adjustments. It requires not only the skill of the doctor and the surgeon, but also the scientific application of the principles of social work. Expert employment service and scientific social work are necessary additions to his skill, and must generally be provided from other sources.

The bulk of industrial medicine and surgery arose out of the requirements placed upon industry by the workmen's compensation acts. When industry became responsible for payment for all accident occurring, it was found advantageous financially to take care of the wounds of industrial workers by employing a physician to come into the factory for surgical or medical work. Some industries found it advisable to employ physicians for several hours per day to attend to minor injuries by immediate treatment, thus preventing worse conditions from developing, and to take care of injuries so as to restore to working capacity sooner than otherwise would be the case. In either instance the dollar was the motive. Industry was concerned with saving the money which they would

\*Presented before the Fifteenth Conference of Industrial Physicians and Surgeons, Harrisburg, Pa., May 25, 1922.

otherwise have to pay in compensation, or in increased insurance rates. Many physicians and surgeons summoned into industry began to grasp the full significance of medicine as related to industry and industrial workers, and to enlarge their view to comprehend the whole health of workers in industry. They have been the leaders in attempting to make industry safe for the workers and the workers safe for the industry.

The beginnings thus made are bound to grow. Industrial medicine has a great future. The industrial physician will by no means do the whole job of promoting the physical well being and safety of workers, but he will be an important factor. Linked with him will be the employment department, scientifically engaged, the service department, and the department of social welfare. All of these departments, including the medical, will eventually be organized on a mutual or cooperative basis. The function of industrial medicine will become a cooperative enterprise of employer and employee, with perhaps the public taking an active part for

the good that may come to the community. One of the serious weaknesses of industrial medicine today is that it is not cooperative, and does not enlist the financial interest of the employee. It cannot receive the full moral support of labor unless labor has a hand in its management and a burden in its support. Too many industrial physicians take the point of view of the employer. From observation covering some years, I am convinced that industrial physicians and surgeons, with many brilliant exceptions, are unsympathetic with labor and labor unions. There can be no permanent success with such an attitude. It is contrary to the best conception of industrial medical work. Labor unions and cooperative labor groups will fill a more important place in the future than in the past. Industrial medicine must establish itself on the solid ground of industrial peace by taking neither side and by establishing close communication with the human material with which they must deal among the industrial workers and employers. Science takes full account of every factor.

window cleaning has come to be a trade, and men equipped with ladders, pails, brushes, squeegee and other material engage in this occupation. In many buildings, however, the work is left to factory hands who with little equipment carelessly clean the windows.

The failure to clean light bulbs, reflectors, globes, and diffusers of an artificial lighting system results in just as serious loss of illumination as neglect in cleaning windows. Soap and water are the materials most generally used for the cleaning of glassware of lighting units. In some industries special cleaning preparations must be used to remove the specific sort of dust raised.

The cost of cleaning windows is balanced by the saving on lighting bills. A New York City department store seven stories in height and with a basement employs a man at \$23.00 a week to clean the electric light globes and fixtures of the store. The cleaning is done at night with each unit in place. The average cost of cleaning each light averages about six cents per unit. They are cleaned every eight days. And the firm receives almost the full benefit of the money it expends for illumination.

Walls, ceilings, and columns constitute a secondary source of light, for much depends upon the reflective surfaces in obtaining a uniform distribution of light in the room. Newly painted white walls will reflect from 70 to 80 per cent of the light they receive; yellow walls reflect 55 to 65 per cent; dirty tan walls reflect from 25 to 40 per cent of light. Care should be taken, however, that the plain white should not produce a glare.

## Clean Windows an Economy

THAT cleanliness produced by mere soap and water and a soft rag is economy is the contention the New York State Department of Labor is urging on factories within its boundaries. Clean windows, clean lighting fixtures, white painted ceilings, light tinted walls, and white machinery will increase the illumination thereby reducing eyestrain, fatigue, and accident, and promoting health. In the belief that merely by keeping lighting facilities in a state of cleanliness many workshops can bring their illumination up to the minimum required by the new state lighting code, the department has issued a bulletin setting forth the economic value of maintaining clean windows and lighting fixtures.

The ideal of every workshop should be to secure as much sunlight as possible, and failing in this to resort to artificial light as much resembling the deflected rays of the sun as possible. Dirt on windows, on lamps and fixtures causes a wasteful absorption of light. Indeed, authorities in the past have made allowance for the accumulation of dirt on bulbs by increased lighting intensity.

Inspection has disclosed workshops which, had their windows been cleaned, would have reduced consider-

ably their cost of illumination. Windows blocked with materials, windows with partitions near them, windows covered with signs and letters and painted designs have been found which excluded a great amount of valuable daylight.

Many stores and factories realize the value of clean windows. In fact,

Windows of a factory found to be coated thickly with dirt and lint through which daylight was supposed to enter. After cleaning with soap and water, 29.74 per cent more light was admitted than at the time when the photograph was taken.

# Eyestrain in Industrial Occupations\*

BY NELSON M. BLACK, M.D., MILWAUKEE, WISCONSIN.

**E**FFICIENCY is one of the side bars of the ladder to success and visual efficiency is of the utmost importance in all industrial occupations. The fact that many totally blind individuals are economically efficient does not tend to mitigate the above statement. The real problem therefore is: What is the effect of eyestrain on efficiency in industrial occupations?

Generally speaking vision may be considered as that process whereby light, color and form are recognized, and is conceded to be the result of the physiological action of light in the composing of a photo-chemical substance contained within the retina or nerve-bearing coat of the eyeball. Hence light or illumination is of prime importance in visual efficiency. The ability of the normal eye to distinguish the form of an object depends upon three factors: (1) the size of the image received upon the background of the eye; (2) the amount of light reflected from the object; (3) the contrast of the object with its background. An object can be recognized by the so-called normal eye if the angle subtended by it upon the retina equals five minutes and its component parts, as for instance a letter, subtend a 1-minute angle. The amount of light reflected from the object must be sufficient to decompose the photo-chemical substance within the eye and cause a stimulation of the optic nerve endings. The coefficient of reflection between the object viewed and its background must differ sufficiently to make a contrast, otherwise the object will be invisible.

All rays of light reflected or emanating from objects twenty feet or farther away are practically parallel. The normal eye when at rest is in focus for a distance of from twenty feet to infinity. When an object is closer to the eye, say at the reading or working distance of fourteen inches, the rays of light emanating from the print or object worked upon are divergent and must be converged or be brought to a focus upon the retina to produce a clear image.

In order to obtain a clear picture with a camera it is necessary to have the plate or film at a focal point of the lens. With the eye it is necessary to have the retina at the focal point

of the lens. With the camera, the lens is moved forward or backward from the plate; such a movement is manifestly impossible in the eye. What does take place is called the act of accommodation and is a physiological process of the lens substance. The lens of the eye is enveloped by a capsule; attached to the margin of this capsule is a delicate circular ligament which in turn is attached to a muscle in the anterior segment of the eye. The lens substance within its capsule is an elastic material which constantly tends to take the form of a sphere. When the controlling muscle is at rest the ligament attached to the capsule holds the lens substance in a flattened form and the eye is accommodated for parallel rays. When the rays become divergent the muscle contracts; this relieves the tension on the ligament and capsule and the lens takes on a more spherical form and focusses the divergent rays on the retina.

## Causes of Eyestrain

The constant use of the muscle controlling the mechanism of accommodation in normal eyes for any near work is fatiguing and productive of strain which can only be relieved by short intervals of rest. In normal eyes strain is induced by improper illumination and by lack of contrast in the color and background of the materials worked upon.

Under proper illumination eyestrain results from: (1) substandard vision due to congenital deformities of the eyeballs; (2) lack of perfect harmony in the action of the muscles controlling the movements of the eyeballs; (3) some defect in or disease of the eye itself. The subject of illumination as a factor in eyestrain is important. Quoting from the chapter on eye conservation in "Waste in Industry" by Dr. Earle B. Fowler, "the simple requirements on which efficient illumination is based are: (1) light enough to see to do work—too little or too much producing discomfort; (2) diffusion to avoid sharp contrasts and deep shadows; (3) elimination of glare."

There are various factors which exist in the eye itself which reduce the ability to see distinctly and therefore interfere with visual efficiency. These are known as farsightedness, nearsightedness and astigmatism, and are due to deformities of the eyeball,

which in most instances are congenital.

Farsightedness is the name applied to a condition of the eyes in which the rays of light entering the pupil are brought to a focus back of the retina because the eyeball is too short. Consequently there is blurred vision. Where the eyeball is not too short the accommodation power may be forced to the point where it will converge the rays and focus them on the retina; this causes, after a short time, headaches, pain in the eyes, red lid margins, and inflamed eyeballs. This defect can readily be overcome by placing the proper strength of convex lens before the eyes to converge the rays of light upon the retina and thus relieve the muscles of accommodation of the work.

Nearsightedness is the condition in which the eyeballs are too long, so that parallel rays of light entering the pupil are brought to a focus in front of the retina. These eyes see clearly when the object is close to them, as the reflected rays of light are then divergent and can be focused on the retina. The complaint made by shortsighted individuals is inability to distinguish objects in the distance, vision being blurred even at the ordinary working distance in nearsight of the higher degrees. The defect is corrected by placing the proper strength of concave lenses before the eyes to bring the rays of light to a focus on the retina.

When the cornea, or clear anterior segment of the eyeball, is not the true segment of a sphere the result is astigmatism; in other words, the curvature is greater in one meridian of the front of the eye than it is in the other, so that rays of light entering the eye in the plane of one meridian will not be brought to a focus at the same point as those entering the plane of the opposite meridian, resulting in an irregularly shaped retinal image. This condition is also found associated with either farsight or nearsight and may be corrected by properly adjusted lenses. At or slightly after the age of 40 the ability to read or distinguish details at or within a distance of 14-16 inches is diminished. This is the result of loss of the power of accommodation due to hardening of the lens substance. Such a loss of vision can be brought to normal with glasses which make up the loss of accommodative power.

\*Read before the 11th annual meeting of the National Safety Congress, Detroit, August 28-September 1, 1922.

When an object is regarded (say at 14-16 inches distance, which is the proper reading and working distance), the two eyes must turn toward each other so that both eyes will look at the same point. If the muscles which pull the two eyes together are weak there will be blurred vision after a short period of close work and an eyestrain which will cause a headache, frequently not apparent until the next morning. If the muscles which move the eyes up and down are not perfectly balanced in power one eye will not be brought to the same level as the other, consequently more nervous energy must be sent to the weaker muscle, which results after a short time in pain and discomfort and inability to use the eyes.

Prolonged use of normal eyes under the best hygienic conditions induces fatigue, general and local, with lowered visual efficiency. The rapidity with which the fatigue makes itself manifest is greatly increased under bad hygienic conditions. If, in addition, there is defective vision or imperfect muscle balance further loss in efficiency results from inability to see details and mistakes are made, with consequent reduction in quality and quantity production. The effect upon the eyes of strain due to the above mentioned deformities of the eyeballs, known as "refractive errors," are many and varied, depending upon the degree of error and amount the eyes are used in close work. Congestion or redness of the eyeballs with itching and burning of the lids, the formation of a sticky secretion that dries and forms scale at the roots of the lashes, which tend to fall out, and the formation of abscesses in the lid margins, or sties, are common symptoms.

Use of eyes having defective vision from uncorrected refractive errors for any close work produces blurred vision and usually results in headaches, which may appear in the forehead, back of the eyes, the temples or top of the head; all of which tend to interfere with the general efficiency of the individual. Pain in the back of the head, with occasional dizziness and nausea, the result of using the eyes in the near, is usually due to some lack of power or insufficiency of the muscles which control the motion of the eyeballs and is frequently found in conjunction with refractive errors.

The study made by the Federated American Engineering Societies of industrial operations shows that more than 25,000,000 men and women are employed in the United States with substandard vision requiring correction. This is an astonishing state-

ment but corresponds with the result of the visual tests made in public schools throughout the United States. These examinations show 20 to 25 per cent of school children have substandard vision. Newton Fuesle of the *Outlook* attributes this large percentage of defective vision to the fact that evolution has been unable to keep pace with the change in environment and use of the eyes.

#### Substandard Vision Correction

Manifest errors of refraction, in many instances, are not as productive of eyestrain as those in which the error is latent, i. e. masked by the well-developed power of accommodation, for the reason that the visual defects are so great that the muscles of accommodation cannot and do not attempt to overcome them. In the latter cases the lack of efficiency lies in the inability to see details clearly. In latent errors of refraction the ordinary visual tests will not detect the visual defect, but the symptoms following continued close use of the eyes are unmistakable. For this reason glasses to correct even small visual defects are important and necessary in near work to relieve eyestrain. By the proper selection of glasses the inability of farsighted, nearsighted and astigmatic eyes easily and comfortably to see may be corrected. The insufficiency of the muscles which move the eyes may be overcome in some instances by proper training and exercises, in other cases glasses which correct the refractive errors will bring about the relief; occasionally it is necessary to resort to operative means.

The necessity for the physical examination of individuals, male or female, applying for positions in any manufacturing establishment is a hobby of the writer and will be apparent upon a little thought. For instance, no manufacturer, factory superintendent or foreman would accept or install a machine without inspecting it to see if it were complete in every detail and in good working order. Every employee is a part of the whole working machine of the factory and any defect in any one part affects the whole. For example, a person with one-fourth, one third or even one-half of standard vision cannot be considered as competent a workman as one with standard vision. Again, one may have standard vision according to the test but may have farsighted or astigmatic eyes. The use of the eyes for detail work for long periods under such conditions causes eyestrain which results in pain and discomfort

in the eyes, and in headaches, and thus interferes with the efficiency of the individual.

In a very large proportion of the cases of poor sight, properly fitted glasses will correct the vision and if a rule existed requiring physical examination, as suggested above, men with poor vision would find out their difficulty when applying for a position and would, if possible, have their sight improved by glasses. This would prevent many accidents, as well as relieve the individual from eyestrain and headaches, and also enable him to do work much better and more easily. In many cases the glasses would be a protection against eye injuries. Another factor which should be kept in mind, while speaking of eye examinations for applicants for a position, is the payment of indemnity for loss of vision in case of accident to the eye. If there were a record of the man's vision made at the time he was employed and through an accident he lost one-half or all of the vision of an eye the basis of settlement would at once be determined without the man's having to pay a lawyer to fight his employers and try to prove he had perfect vision before the accident.

Further, poor vision or inability to see well may be a factor in causing general accidents, because a man with poor vision cannot see the details of his work or the parts of the machine with which he is working sufficiently well to protect himself against injury. Again, his vision may be so poor that he cannot see to get about the shop without running into objects or machinery in motion, which might cause an injury, especially if the general lighting is poor. It may be said, of course, that such a man should not be employed in such a place. That is true enough and such would not be the case if every man who applies for a job had to submit to a physical and visual examination as one must before enlisting in the army or navy or when applying for a position in railroad or street car service. With a knowledge of the visual ability of an applicant he can be placed in a position where visual defects will be less of a handicap to himself and less of a menace to fellow employees on the one hand, and be informed of his visual shortcomings and directed as to means of obtaining relief on the other.

A letter of inquiry to Dr. Harry E. Mock of Chicago, Ill., relative to physical examinations in industrial corporations elicited the following illuminating reply:

Figures are not available as to the number of industrial corporations hav-

ing physical examinations. Many corporations have reported that they have, but on investigation one finds their physical examination is a mere inspection by a doctor and oftentimes by a nurse. From my studies of the various systems in vogue in other plants and from the reports of Dr. Clarence Selby of Toledo, Ohio, who investigated industrial hygiene for the U. S. P. H., we have estimated that approximately 150 representative industrial corporations in this country really have an adequate system of physical examination of employees. Approximately an equal number of industries require determination of visual acuity.

Unions object to the physical examination of applicants for work, on the ground that employers often use this as a subterfuge for rejecting labor leaders or so-called undesirables in the labor ranks for employment. They object to the examination of employees on the ground that many industries discharge employees who are found to have physical defects and that these men are unable to secure employment elsewhere because of these discharges. Also they claim that the doctor will sometimes find some alleged physical defect and recommend the work as being too hard for that individual when no defect is present and the only desire of the management is to find some excuse to discharge a union man. These are not specific charges but are conditions insinuated by the unions.

The real facts of the case are that some large industries have rejected as high as 15 or 20 per cent of the applicants examined for work. This means that these industries are picking only the physically fit and are not taking their share of the burden by selecting suitable occupations for the slightly handicapped worker—occupations in which the handicapped man can be 100 per cent efficient if proper selection of the job is made. In these industries, where the best form of industrial medicine and surgery is practiced, the percentage of applicants rejected for work ranges between 1 and 3 per cent. These medical departments reject an applicant *only* when he has some condition which makes his presence in the plant dangerous for himself, his fellow workers or for property. All other applicants who have defects are considered and placed according to this formula—physical qualifications plus occupational qualifications equals the job.

Fortunately a great many industries are yearly obtaining this broader vision and are utilizing physical examinations, including examination of vision, for the purpose of scientific placement of men on jobs. They realize that it is an efficiency measure par excellence. Naturally, labor unions are gaining a better viewpoint regarding physical examinations and the objections formerly heard are gradually being wiped out. Mr. Gompers has assured me that if industries would adopt physical examinations from the broad humanitarian standpoint above outlined labor unions would be absolutely in favor of this procedure.

The following is quoted from "Waste in Energy": "As in the cor-

recting of other factors of occupational hygiene, standards have been set, so, after further study, visual acuity standards will have to be determined for each grade of workers and readjustments made, with alterations in our methods of testing acuity to suit conditions, until these standards give us the necessary minimum for each kind of work. As examinations are made at present any set level would exclude workers shown by practical test to be very efficient producers.

"Many subnormal eyes will work well even for fairly trying work if conditions are good. Therefore it is first of all urgent to bring the working conditions up to the best, on the basis now understood."

### State and Federal Labor Reports Simplified

Duplication of work by the state and Federal Department of Labor in the collection of employment statistics has been eliminated through a plan that has been adopted by the respective departments which became effective in July. As a result of the new arrangement the work of the United States Employment Service in the collection of employment reports has been discontinued, while the work of the United States Bureau of Labor Statistics has been expanded and the New York State Department of Labor is furnishing from its regular monthly reports that have been collected since 1914 all New York State's reports that are required by the Federal Bureau.

Manufacturing concerns throughout the State which have been reporting to both the State and the United States government have received the news of the new plan with much satisfaction, as it eliminates unnecessary work. Heretofore the firms reporting to the State Department of Labor have also been asked to make similar reports to the United States Employment Service, but the new plans eliminate this duplication of reports. Now the reporting firms will send in but one report, the one to the State Department of Labor, which will furnish a transcript of the report to the Federal Bureau of Labor Statistics.

The cooperation between the State and Federal Bureau of Labor Statistics was begun several years ago and now is being considerably extended in connection with the new plan for the collection of employment data for the country as a whole, which resulted from the recommendations of the Committee on Employment Statistics

of the President's Unemployment Conference.

### Engineering Occupational Index Compiled

An engineering occupational index is being compiled by the Committee of Classification of Engineering Positions recently appointed by the American Association of Engineers. The committee consists of A. B. McDaniel, educational specialist, War Department, chairman; C. B. Mann, Civilian Advisory Board, General Staff, War Department; Prof. C. J. Tilden, Yale University; J. R. Randall, president, Rochester Mechanics Institute, and W. C. Bolin, pilot engineer, B. & O. R. R., Baltimore, Md. E. O. Griffenhagen, J. L. Jacobs of Chicago, and Prof. H. T. Stock of the University of Illinois are advisory members of the committee.

The index will be of value to employment organizations in the selection and allocation of engineers, to licensing boards, civil service commissions, and similar organizations and to individual engineers.

### Canaries in Mine Rescue

International News Reel. A special cage for the carrying of birds and mice by rescue parties in mines has just been completed by English mining engineers. The cage is air tight, and made of aluminum, with mica windows at the ends and sides. When rescue parties, at work in the mines, wish to test the air, the door of the cage is opened to admit the surrounding atmosphere. The slightest trace of carbon monoxide makes the bird or mouse insensible. Oxygen is stored in a small cylinder on the outside of the cage, and the release of a small valve sends a sufficient supply inside the cage and the inmate is thus revived. Numerous experiments have been made to prove the worthiness of this plan, and in all instances have proved successful so that the British Bureau of Mines has passed on the device. In all cases, the birds, usually canaries, have done their heroic work and have not died. They are being specially bred so as to secure the best species.

## The Basis of Efficiency

THE efficiency of the human organism and the factors which influence this efficiency, as one of the most important problems of the present day, were discussed by Dr. E. P. Cathcart before the Section of Physiology of the British Medical Association recently. Physiological laws are the basis of any accurate gauge of efficiency and must be reckoned with as a factor in industrialism. The large proportion of substandard lads recorded in the National Service Report he calls an aftermath of the rampant industrialism of the past century when children of both sexes at the early age of seven were subjected to twelve or even fifteen hours of labor under conditions that are no longer tolerated. That England is still paying the penalty of the older order of industrialism is proved by the higher percentage of rejections among town and factory workers. The physiologic inefficiency of the English people is best attested by the report on preventive medicine by Sir George Newman which shows the minimum average annual loss of time through sickness amounts to 14,295,724 weeks, or a period of upwards of 270,000 years, and this figure did not include absence from work due to maternity benefit, sanatorium treatment, or absences for less than four days per patient.

Much importance must be attached to wide individual differences not only in the capacity to perform work, but in "will to work." As it is impossible to make quantitative determination of the degree of fatigue in a given subject, fatigue studies are usually carried on by measuring the capacity of the organism to carry on under varying conditions of speed, load, rhythm, rest, and work habits. It is significant that the study of metabolism has so far given no clue to the onset of incapacitating fatigue. Benedict and Cathcart found in their experimental work that subjects on the verge of absolute collapse from fatigue evinced, so far as metabolism goes, no marked evidence of diminished efficiency. It may be definitely stated, however, that an insufficient intake of food, or the consumption of poor or inadequate food is one of the chief sources of general inefficiency. The body is able to withstand even complete deprivation of food for comparatively long periods, but this carries with it a corresponding depression of capacity to perform

external work.

This phase of the subject has not received the attention it deserves, according to Dr. Cathcart. Two sets of observers have worked on it. Benedict and his co-workers reduced the food intake of an experimental group over a period of four months, so that there was a loss of 12 per cent of the body weight, but so far as laboratory tests were concerned no marked diminution in muscular power took place. The subjects complained of feeling weaker and less capable.

### Food Quality Important

The other recorded experiment is that of the condition in Germany during the war years where the far-reaching effects of chronic under-feeding resulted in increased death rate, increased liability to disease, slow recovery from attacks of disease. Professor E. H. Starling's report on these conditions adds that "everywhere the people have lost their vigor and capacity for work," and "all spirit of enterprise is gone." Evidence would indicate, says Cathcart, "that it is not only the quantity but the quality of the food consumed that plays a part in the fitness of the individual to perform hard muscular work. All modern work would seem to point to the conclusion that if the caloric value of the food supplied is adequate, the actual demand for protein is very small. It is very difficult, however, to believe that the far-reaching common belief in the efficacy of a high meat intake, despite scientific evidence to the contrary, is without some foundation. It is possible that the value of meat (flesh) depends not merely on the high biological value of its protein, but also on its stimulation of cellular activity."

Dr. Cathcart places great weight upon the psychic imponderabilia which compose a large part of the average environment. Monotony of tasks is an important factor, and individual temperament important in forming an estimate of monotony. The influence of the cooling power of the air is important, as are factors of lighting, design of machines, etc. The real industrial efficiency of the worker cannot be related to any single factor. The quest of efficiency involves the whole welfare of the race and nation, and for the utmost of co-operative study by the scientific investigator, the employer, and the employee.

## Occupation Hazards and Diagnostic Signs

Realizing that physicians would be greatly aided in diagnosis of symptoms by a knowledge of occupations which cause them, Louis I. Dublin, statistician Metropolitan Life Insurance Co., and Philip Leiboff have compiled a pamphlet on occupational hazards and diagnostic signs which is a guide to impairments to be looked for in hazardous occupations. The pamphlet is published as Bulletin No. 306 by the Bureau of Labor Statistics of the U. S. Department of Labor.

The bulletin is of special use to the general practitioner, the industrial hygienist, and to safety engineers. Nine major hazards are listed: abnormalities of temperature; compressed air; dampness; dust; extreme light; infections; poor illumination; repeated motion, pressure, or shock; and the poisons. Skin irritants are treated in a separate section.

To aid him in detecting the hazards and their effect on the worker, two lists are presented. The first consists of the more common hazardous occupations, arranged alphabetically; the second consists of hazards, together with their effects or symptoms, as well as the occupations affected. After each occupation in the first list is a reference code to the particular hazard in the second list.

The procedure is as follows: After determining the man's occupation the medical examiner should look it up in the first list of hazardous occupations; he can then try to discover if the patient is suffering from any of the symptoms enumerated in the second list under the particular occupation. In this manner, the medical profession will become better acquainted with occupational diseases and will be in position to help discover and eliminate such cases. On the other hand, plant executives and safety engineers must take cognizance of the existence of these occupational diseases and eliminate their causes in their particular establishments. The bulletin will also be of use to factory inspectors, labor officials, and workmen's compensation boards in inspecting and rating industries.

Hot lunches are now served to 187,434 children through the efforts of extension workers of the United States Department of Agriculture and the state agricultural colleges working in cooperation with local organizations and school authorities. More than 10,592 children are buying milk for lunch.

# The Physician and Compensation

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE part that the physician plays in the allotment of compensation may or may not be such as to warrant commendation, but the medical attention given to employees not only at the time of injury but before, as well as following the injury, influences many decisions. The question of negligent care on the part of an attendant physician was passed upon in the case of *Brown v. Sinclair Refining Co.*, 206 Pac. 1042, when the Supreme Court of Oklahoma held that the employer is liable for all legitimate consequences following an accident, including unskillfulness or error in judgment of the attendant physician. The Industrial Commission, it was further determined, has exclusive jurisdiction in such event. But suppose, as occurs frequently, a disease is pre-existent, antedating the injury. In the *Schrieber* case, 240 S.W., 963, the employee had cerebrospinal syphilis which, according to the testimony of the physicians, was the cause of death, and not the injury. . . . But the jury and the Texas Court of Civil Appeals held that the accident was compensable.

That disability from disease either caused or accelerated by an occurrence in the course of employment which is an accident is compensable, was decided in a similar situation which came before the Supreme Court of Utah (206 Pac. 278) in which a tuberculous condition was aggravated and accelerated by the inhalation of poisonous gases. The Supreme Court of Pennsylvania (116 A. 891) refused compensation in a case where a man was thrown from his wagon over the edge of a bridge into some water. He worked until late that night, developed a cold the next day, and remained at home. He returned to work for twenty-two days when bronchitis and pleurisy developed and he finally died from broncho-pneumonia. The court said that the pneumonia was not traceable to the accident as a natural result therefrom and the statement that injuries were "indirectly responsible" for the pneumonia amounts to no more than "it might have resulted" which is not sufficient. There must be a probable, direct relation shown between the injury, the disease, and the death; otherwise the liability would be fixed by surmise. The same court, however, when the relationship is evident, has awarded

compensation as in 116 A. 889, where an employee sprained his ankle and later developed osteomyelitis followed by tuberculous peritonitis.

The Maine Supreme Judicial Court (117 Atl. 306) affirmed the findings of the Industrial Accident Commission which awarded compensation for death from tuberculosis accelerated by an injury. Here the employer must have known the man's condition at least two years before, when he left and later returned to work. In the *Webster* case (116 Atl. 842) the question of an epileptic seizure was raised. The question as to whether the fall causing death was occasioned by vertigo or epileptic fit was waived by the court as not material to the decision of the case. A second question as to whether the injury was received in and grew out of employment was answered in the affirmative. The Court held that the injuries caused by the fall may have arisen out of employment, even though the vertigo or epileptic fit contributed to the fall. The court adds, "We have found no case in which the claimant has been refused compensation when the accident resulting in the injury or death of the employee was not caused solely by the physical disability of the employee or where it contributed only to the accident."

The Supreme Court of Michigan, 188 N.W. 393, in passing on the cause of death says, "The fact that the plaintiff was predisposed, because of disease, to this form of attack, (to partial paralysis from a hemorrhage in his brain) has nothing to do with the question of what befell him. . . ." Here a watchman who rode a bicycle in making his rounds was injured by falling from his bicycle and in attempting to save himself by catching at a pile of lumber suffered an accidental injury.

A recent holding of the Supreme Court of Michigan, 187 N. W. 400, declares that death from shock arising from an accident occurring in the course of employment compensable. "In the instant case Mr. Klein could not anticipate that, when he removed the register, it would slip from his hand, nor could he anticipate it would hit a fellow employee, rendering him unconscious, nor could he anticipate that he himself would receive a shock which would so affect him in his weakened condition that he would as

a result thereof, pass away in less than three weeks. This, however, was just what happened in the opinion of the attending physicians and the other doctors. This was also the conclusion of the Industrial Accident Board."

The Industrial Accident Board, acting within its powers, held the facts to be conclusive and the award was affirmed.

This last case is the first of its kind to be decided and the question is raised, is it justifiable and reasonable? The original participants, the employer and employee, were entirely unaware apparently of the possibilities of their relationship, the employer of his employee's physical condition, the employee of his own physical condition and the possibilities of his work. The fundamentals of physical examination, job analysis, and vocational alignment seem scarcely discernible at times. There is really a wanton expenditure to meet end results but it is a fiction that we plan carefully to alleviate the necessity for such expenditure.

THE Supreme Court of Michigan, June 5, 1922, declared that the provisions of the Workmen's Compensation Act are applicable to "all ages."

The amount to be awarded is in no way dependent upon the probability of a more speedy and complete recovery by a person young in years than by one of advanced age. It depends entirely upon the nature and extent of the disability and wages earned. So long as the disability continues, the payments must continue, within the limits fixed by the act. Any attempt to determine that a part of the disability is due to an injury from which there has not been a recovery, and a part of conditions incident to old age, would be entering upon a field of speculation, which we think neither the board nor this court should be at liberty to explore.

It was held that a rehearing could not be had before the Industrial Accident Board, to review facts not establishing the liability as found by the board, but the amount of weekly payment ordered due to the changed physical condition of the party injured, may, however, "be ended, diminished, or increased, subject to the maximum and minimum amounts," if the facts proved warrant such action.

—*Lebourneau v. Davidson*, 188 N.W.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Federal Health Work Among the Indians\*

An Account of the Health Section  
of the Bureau of Indian Affairs

BY JAMES A. TOBEY, NATIONAL HEALTH COUNCIL, WASHINGTON, D. C.

SINCE the original inhabitants of the United States were the Indians, the Federal Government has been concerned with Indian affairs from its beginning. Laws regulating trade with the Indians were passed in the early days of the Republic and the office of Superintendent of Indian Trade was created in 1806 lasting until 1822. In 1824, a Bureau of Indian Affairs was established in the War Department by the Secretary of War. In 1832, Congress passed a law which created the Office of Commissioner of Indian Affairs and continued it in the War Department. When the Department of the Interior was formed in 1849 the Office of Commissioner of Indian Affairs was transferred to it, where it has been ever since.

The only order on record dealing with health while the Indians were under the jurisdiction of the War Department seems to have been one concerning the moving of Indians from one country to another. In this order, it was stipulated that care should be taken that the best sanitary conditions prevail and that their health be carefully guarded. Physicians were employed during these days, though more for the benefit of the government agents than for the Indians. Army surgeons were generally accessible and were frequently called upon to render medical care.

In 1873, the first organized effort was made to deal with the health of the Indians. In that year, a division of medicine and education was estab-

lished in the bureau and continued until 1877. There was a great need for such work as disease had been a potent factor in decreasing the American Indian population. As early as 1865, a Senatorial committee had stressed this rapid decrease and had attributed no small part of it to contact with civilization and consequent ravages of disease. In spite of this fact, the division of medicine was discontinued in 1877, not to be revived until 1909, although there was always a certain amount of medical

hospitals has grown from 4 in 1888 to 73 in 1922.

From 1875 to 1922 the number of positions authorized for physicians has grown from 74 to 200, for nurses, 8 to 100; for hospital employees, 7 to 100; and for field matrons from 3 to 75. During the war, and since, the Bureau has not been able to keep all the Health Section positions filled.

The principal diseases with which the medical service has to cope have been tuberculosis and trachoma. For instance, it is estimated that in 1920,

U. S. Indian Sanatorium at Carson, Nev., illustrating a standardized design much in use in hospitals of the Indian Bureau.

service in the field. A few years ago, the Indian race was believed to be a dying race. Recent statistics show that it is a living race. In the absence of devastating epidemics, the annual birth rate exceeds the annual death rate, and individuals live out the normal expectancy of life.

The first hospital for Indians was established in 1882. The number of

there were nearly 25,000 cases of tuberculosis and over 30,000 cases of trachoma among some 200,000 Indians, not including the five civilized tribes. In that year, there were 1,230 deaths from tuberculosis. Six tuberculosis sanatoria schools are now maintained with a capacity of 464 persons and a corps of eye specialists is also employed. Pamphlets on tu-

\*Approved by the Commissioner of Indian Affairs and by Dr. D. B. Armstrong, Executive Officer, National Health Council.

berculosis and on Indian babies have been prepared. In 1913, the general death rate among the Indians was 32.24 per thousand population. In 1918, it had been reduced to 29.42 per thousand population, while in 1920 it was 22.33. The birth rate in 1918 was 29.42 per thousand population and in 1920 was 31.67. These figures include the entire Indian population, except the five civilized tribes where normal birth and death rates are said to exist.

There are at present 336,337 Indians in the United States including the five civilized tribes. Many of the Indians are citizens and tax payers. While the Indians are scattered throughout the country, the largest number, 119,255, are in Oklahoma. In general, the majority are in the states of the southwest and west, as Arizona, New Mexico and South Dakota.

The present Commissioner of Indian Affairs is Honorable Chas. H. Burke of South Dakota. The Assistant Commissioner is Honorable E. B. Meritt of Arkansas. The Health Section of the Bureau of Indian Affairs has at present, the following personnel: Chief medical supervisor, \$3,000\* annual salary; medical supervisor, \$2,250\* annual salary; 6 special physicians at \$1,800\*\* each; 6 traveling nurses, \$840\*\* each; 6 field dentists, \$1,500 each; 100 agency and school nurses; 160 agency and school physicians; 50 contract physicians; 90 field matrons; total of health personnel, 420.

The present chief medical supervisor, Dr. R. E. L. Newberne, was appointed in 1918 after four years' service with the Bureau and thirteen years' service in the Philippine Health Service, then controlled by the United States Public Health Service. The chief medical supervisor directs the employees and facilities of the health service at large, and makes recommendations for the improvement of such service to the Commissioner of Indian Affairs. In addition to his other duties, the chief medical supervisor acts as principal epidemiologist for the Bureau of Indian Affairs. The duties of the medical supervisor are of the same general character as those of the chief medical supervisor, though somewhat more restricted in scope.

The special physicians of the Indian Service are primarily specialists in

the diseases of the eye, ear, nose and throat. They also take charge of epidemics, fill special assignments, and make district and local inspection reports to the Commissioner of Indian Affairs. The Service is divided into six special-physician districts. Traveling nurses accompany special phys-

health personnel, construction and repair of hospitals, purchase of medical and hospital supplies, and all other expenditures for health work, together with the allotment of funds for such purposes. Instructions are issued through the superintendents to the field personnel and directly to the

A typical ward in the Carson Indian Sanatorium.

icians, assisting them in the work and taking care of all patients operated on or treated by the special physicians. Field dentists travel from jurisdiction to jurisdiction in the respective districts and perform dental work for the pupils of the schools and for the reservation of Indians. The Indian Service is divided into seven dental districts.

The difference between agency and school nurses is in most instances a difference of funds from which they are paid. An agency nurse is paid from agency funds and a school nurse from school funds. The duties are practically the same when they are employed in an agency hospital or a school hospital.

The improvement of home, educational, moral, sanitary environmental and social conditions is regarded as the primary object of field-matron effort for the advancement of the Indian people. The field matron comes into the closest relationship with the family and has the best opportunity to influence the home circle, especially the mother and the girls; therefore, she is particularly charged with the duty and responsibility of developing the higher standards of living, or inculcating a desire for progress, and of evolving plans to make the home more attractive.

The administrative duties of the Health Section in the Indian Office include the approval of changes in

traveling physicians and dentists. Forms for reports are prescribed and examinations made and action taken upon such reports of special physicians, field dentists, regular physicians, field matrons, and hospitals.

Appropriations to the Health Section of the Bureau of Indian Affairs for the purpose of relieving distress and the prevention of contagious diseases among Indians have increased from \$40,000 in 1911 to \$370,000 in 1922.

These appropriations do not include all that is spent for health purposes but simply the specific appropriations made for "relieving distress and preventing disease among Indians."

The health section has always worked in close cooperation with the other Government departments. It has kept in close touch with the U. S. Public Health Service. The pamphlets of the Public Health Service on sanitary engineering and control of various diseases have been widely distributed on Indian reservations. The Public Health Service made a survey in 1913 of health conditions among Indians, for which purpose \$10,000 had been appropriated by Congress. The survey revealed the existence of a large number of cases of tuberculosis and trachoma. In 1919, the Committee on Indian Affairs of the House of Representatives held hearings on the conditions of various tribes of Indians and among other things considered

\*Allowed transportation expenses and a per diem of \$3.50 in lieu of subsistence when in the field in addition to salary.

\*\*Allowed transportation expenses and actual subsistence expenses not to exceed \$3.50 a day when on duty, in addition to salary.

the possibility of having the Public Health Service take over the health activities of the Bureau of Indian Affairs. At that time, Surgeon General Rupert Blue of the Public Health Service appeared before the Committee and recommended that the Public Health Service should not take over

this work. The Bureau of Indian Affairs was also opposed to such a step. It was said that the medical problems of the Indian Service were closely blended with the educational, social and industrial problems which concern a race in a critical social and economic transition. During the in-

fluenza epidemic, the Public Health Service detailed 362 temporary physicians for work among the Indians. The health section of the Bureau also cooperates with other Government Departments and with organizations for social service for bettering the living conditions of the Indian.

## Program for the Prevention of Delinquency

### Commonwealth Fund Applies New Remedies at Strategic Points

BY BARRY C. SMITH, COMMONWEALTH FUND, NEW YORK CITY.

THE Commonwealth Fund stands sponsor for the various activities which have been undertaken under this program, but it is not in any sense an operating agency in carrying them out. It has rather attempted to gather together into a coordinated whole a number of organizations equipped with knowledge, experience, and staff necessary to the conduct of the work. These operating organizations are the New York School of Social Work, the National Committee for Mental Hygiene, the Public Education Association of New York, and a Joint Committee on Methods of Preventing Delinquency, especially organized for the purpose. It should be stated at the outset that the program for the prevention of delinquency, which this article attempts to describe, is not intended to cover the field in any comprehensive way. It rather attempts, with the emphasis on prevention, to assist in the development of certain somewhat new implements and to apply them at certain strategic points where it is believed they will prove most helpful.

Nearly two years ago the Board of Directors of the Commonwealth Fund tentatively adopted the field of child welfare as a major interest. There followed a process of evolution in the program. In January, 1921, Mr. Henry W. Thurston, of the Department of Child Welfare of the New York School for Social Work, was engaged by the Fund to make a thorough-going study of the needs and possibilities in the field of child welfare. In June of that year Mr. Thurston presented a complete report covering a wide range of activities and suggested certain possibilities both in connection with work for dependent, neglected, and delinquent

children and for children in general. After careful consideration of this report, the Board of Directors, at the final meeting in the spring of 1921 adopted a resolution which in effect called upon the General Director to prepare a program dealing with the subject of delinquency, and to include such subjects as visiting teachers, juvenile courts, and psychiatric clinics, with the possibility of an ultimate annual expenditure not to exceed three hundred thousand dollars.

With this guiding resolution and the large amount of available material gathered by Mr. Thurston, the task of shaping a program proved to be a comparatively simple one. In the discussion of the subject at the meeting above referred to, two cardinal principles were emphasized. In the first place, it was felt that, in accord with the more advanced opinions held by social workers of real vision, emphasis should so far as possible be laid upon preventive work. While it was admitted that reformatory and prison conditions were far from good, and that there was great need of reform in this connection, it was nevertheless believed that far greater opportunities were presented in an attempt to deal primarily with prevention. The program, therefore, has not attempted to deal with delinquency beyond the stage of the juvenile court and probation system. Work with children in the earlier stages is, in the opinion of the Commonwealth Fund, far more hopeful, both as to the children served and as to general beneficial results to the country at large, than an effort to salvage the human wrecks who so largely make up the population of our penal institutions and who are, comparatively speaking, little amenable to treatment.

Secondly, it was felt that in the field of prevention of delinquency,

there were available effective implements which could be developed so as to achieve greater and more far reaching results. It is the purpose of the program to assist in development along these lines. In this connection there appeared to be at least three considerations of fundamental importance:

(1) It seemed fairly obvious that among the prime essentials, in any attempt to prevent juvenile delinquency, was the necessity for a thorough understanding of the complete make-up, mental and physical, of the child tending toward delinquency; and in this fact lay one great value of psychiatry. Again, (2) it appeared of the very greatest importance to utilize to the fullest possible degree the school contact with the child, and it was believed that great possibilities lay in the development of the visiting teacher movement in this connection. (3) It was clear that any adequate plan for the prevention of delinquency must necessarily require a great increase in the number of social workers specifically trained for particular work of this type. With these matters in mind, the program was prepared under four sections, which I will attempt to describe very briefly.

*Section I.*—The work of Section I was entirely entrusted to the New York School of Social Work under the administrative direction of Mr. Porter R. Lee, the director, and Dr. Bernard Glueck, of the mental hygiene department. Under the program there has been established the so-called Bureau of Children's Guidance, a psychiatric clinic, primarily organized for training purposes. This clinic has established, among its other contacts, a relationship with five public schools in the city of New York, from which difficult children are referred to the clinic. In each

\*Read before the Forty-ninth Annual Meeting of the National Conference of Social Work, Providence, R. I., June 22-29, 1922.

of these five schools there has been placed a visiting teacher operating under Section III of the program as described below. These teachers, in the course of their daily work, find many opportunities to bring to the clinic those children who are in special need of careful psychiatric diagnosis and special treatment based upon it. Children from these schools as well as from other sources with which contact has been established, not only receive careful treatment, but the clinic also serves as a training center for students from the New York School of Social Work and elsewhere. It is giving special attention to the training of psychiatric social workers, of visiting teachers, and of probation officers for service in connection with juvenile courts.

There have also been established at the New York School of Social Work fifteen annual scholarships of \$1,200 each for students preparing for either of the above three named lines of work. In addition, the school is offering small scholarships for summer courses to students of experience and promise in the same fields. Very careful courses have been worked out by the school faculty in all three subjects.

This section of the program, therefore, may be said to have two definite purposes. In the first place, through the actual service of the clinic to the school children of delinquent tendencies, it aims to be of real service to the children themselves, and to point the way in determining methods for the prevention of delinquency among school children. At the same time, it provides a training center in connection with the school and the scholarships referred to and will result in an increase in the number of really well trained persons for work in this field.

*Section II.*—Mr. Thurston's report above referred to calls particular attention to the haphazard way in which delinquent children are handled by the many juvenile courts throughout the country. It would seem to be a *sine qua non* that in the juvenile court, the Judge who is to make anything like an intelligent disposition of the young offender who comes to his attention, must know accurately and in full detail the make-up of that particular child. Probation officers should be in a position to give the Judge something upon which to base the decision. Unfortunately a very large percentage of probation officers are not especially well-trained for their work, and, even where there is a well trained officer, it is

impossible for him to present to the court any thorough-going analysis of the particular child involved unless he has at his disposal a means of making a thorough, scientific diagnosis. At the time Mr. Thurston wrote his report, only 17 per cent of the 2,391 courts having jurisdiction over children's cases had facilities for any kind of a mental examination, and in fourteen states no psychiatric or psychological examination of children coming before the juvenile court was given.

#### Psychiatric Field Service

In the light of these circumstances, the Commonwealth Fund decided to establish under its program a traveling psychiatric field service which would serve juvenile courts and also cooperate with public school systems and social agencies in different communities. This work was entrusted to the National Committee for Mental Hygiene. That organization, which has accomplished much in this field under the direction of Dr. Thomas W. Salmon, at once established a Division of Delinquency under the direction of Dr. V. V. Anderson. The first clinic began its work in February. This clinic, which has had the benefit of the personal direction of Dr. Anderson, is ably staffed. Dr. Thomas Heldt is the psychiatrist in charge, assisted by Dr. E. K. Wickman, psychologist; Miss Mildred Scoville, psychiatric social worker; and Miss Margaret Cavender, secretary. Announcements were sent out offering the services of the clinic to cities which have juvenile courts. A large number of pressing requests, for the service were received almost immediately and the clinic, when established, made its first stand in the city of St. Louis. In the latter part of April, Dr. Anderson reported that the clinic was making very real progress; that he had received an unexpected degree of cooperation from St. Louis people; that the Board of Health and other public departments had placed the services of their staffs at the disposal of the clinic and a number of trained workers had offered their services on a volunteer basis. By the first of the present month (June, 1922) the work had progressed to a point where the National Committee for Mental Hygiene felt warranted in establishing a second clinic, and, at the June meeting of the Commonwealth Fund, an additional appropriation was voted for the establishment of this clinic. It is expected that the first clinic

will remain in St. Louis until fall and that the staff of the second will spend two or three months in St. Louis while the technic and method of procedure are being finally worked out. Beginning with the fall there will therefore be available to communities requiring these services two such clinics.

This feature of the work has aroused unexpected interest. A special consulting committee has been organized by the Committee for Mental Hygiene consisting of the following persons: Dr. Thomas W. Salmon, medical adviser of the National Committee for Mental Hygiene, chairman; Dr. Lewellyn F. Barker, of Baltimore, specialist in internal medicine; Dr. Walter E. Fernald, superintendent of the Massachusetts School for the Feeble-minded, Waverly; Professor Arnold Gesell, professor of child hygiene and director of the Psycho-Clinic of Yale University; Hon. Charles W. Hoffman, Judge of the Division of Domestic Relations of Hamilton County Court of Common Pleas, Cincinnati; Dr. Charles H. Judd, professor of education of the University of Chicago; Miss Emma O. Lundberg, director of the Social Service Division of the Children's Bureau, Washington; Mr. J. Prentice Murphy, secretary to the Children's Bureau, Philadelphia; Mr. Herbert C. Parsons, deputy commissioner of the Commission on Probation, Boston.

In general, as indicated above, it is the purpose of this service to demonstrate to those communities which desire it, the value, in handling delinquent and pre-delinquent children, of a thorough-going psychiatric examination and, so far as possible, to assist in establishing work of this character on a permanent basis in the community served. It is expected that the clinic will remain from three to six months in any given community, and it is hoped that during the five years for which this program runs there will result a great development of well organized psychiatric work in connection with juvenile courts.

In addition to this psychiatric field service, the National Committee for Mental Hygiene has established a special psychiatric clinic in Monmouth County, New Jersey, already at work in connection with the general child welfare experiment and demonstration being conducted in cooperation with public authorities and social agencies in that county. This clinic, under the direction of Dr. Christine Leonard, psychiatrist, is making an examination of all school

children and is working in direct cooperation with a visiting teacher supplied under Section III of the program.

*Section III.*—Under this Section an attempt is being made to develop the technic of visiting teacher work and to extend the visiting teacher movement. In view of the very obvious value of the visiting teacher in the school system, it is astonishing that the movement has gained so slowly. A report, issued by the National Committee on Visiting Teachers in June, 1921, indicates that only twenty-one cities in the United States employ visiting teachers.

The underlying factors and conditions which bring about delinquency may be said to date back on the environmental side almost, if not, quite, to babyhood days; on the physical and mental side frequently to prenatal and hereditary influences. Children of defective mentality make up, after all, but a very small portion of delinquents; a large majority of mentally sound delinquents receive their first impetus toward wrong doing from the conditions under which they live. A drinking or brutal father, a negligent or immoral mother, lack of proper parental discipline or too rigorous discipline, home conditions due to poverty, failure of foreign born parents to understand American ways and hence their American children, lack of sympathy and understanding, easily remedied, but neglected, physical defects, etc., are among the many conditions which influence a child toward delinquent acts. Inability, or unwillingness, of a parent to provide spending money often leads to juvenile stealing; a child who has overmuch work to be done at home neglects his school work, and this may speedily affect his conduct.

Miss Edith Abbott, of the University of Chicago, has called attention to the great influence possessed, potentially at least, for the prevention of delinquency by the school teachers of the country. She says: "The school teachers of the United States, if they can be socialized, can accomplish more to prevent delinquency than all the social workers together." This statement is based on the recognized fact that the greater part of delinquency is caused by family and neighborhood conditions, and by the further fact that the school teacher, provided she is alive to it, has unequalled opportunities to observe the first signs of undesirable tendencies on the part of the child; for any

child, who is tending in any way toward delinquency, invariably indicates that something is amiss by his school conduct, work, or attitude. In the school, therefore, where a child spends a large part of his day, lies the best chance for observation and for taking the measures to prevent the development of such tendencies. To the teacher lies open the way to establish a sympathetic understanding with the home, to confer with the parents through their natural interest in the child's school life, and to study the child and his difficulties in the atmosphere of his daily life at home, at school, and in the neighborhood.

The most successful effort, therefore, to catch the earliest incipient tendencies toward delinquency is likely to be directed through the school. It is from this fact and similar considerations regarding other difficulties of the child that the visiting teacher movement has largely taken its beginnings. It is obviously of great importance that every effort should be made to train the ordinary class teacher along these lines, to see to it that she does not judge her pupils solely in terms of reading, writing, and arithmetic, and to help her to become alive to the fact that the child's home influences, or the playmates he may have, affect his conduct; that this little girl has to help her mother too much; that this small boy's apparent laziness may be due to his eyes. But in the school systems of our cities, the ever increasing professional duties of the teachers, the large classes, the many meetings, the quantity of outside work to be done, preclude any possibility of her establishing the close individual contacts with the child and his home which are necessary for good results. Educational authorities who have studied the subject agree in the opinion that this should be the work, at least in the large cities, of the visiting teacher. That she can accomplish valuable results has been definitely proved. Moreover, wherever she has been tried she has proved her value in educating the grade teachers to the importance of the point of view above outlined, and in many cases has changed the entire attitude of a teaching force.

With these considerations in mind, the Commonwealth Fund cast about for the best available agency to assist in developing visiting teacher work throughout the United States. Provision was made in the program for the placing of ten visiting teachers in as many different communi-

ties each year. The cost of these teachers is to be met over a three year period, two-thirds of the Commonwealth Fund and one-third by the local community. The Public Education Association of New York accepted this responsibility and sent out announcements of the opportunity offered, to a large number of communities located in the first instance east of the Mississippi River. An astonishing number of applications was received. Nearly two hundred communities desired this service, and it is a somewhat surprising fact that the replies in most instances came directly from the public school systems and not from some civic or welfare agency.

The work under this section of the program has involved many difficulties and has therefore been somewhat slower of development than any other section. It has been necessary to select the communities with great care in order to be sure that the authorities were really in earnest and understood exactly what it was they were asking for. It has also been a difficult proposition to secure visiting teachers who are well trained and who will be satisfactorily adapted to the particular community to which they are to be sent. This difficulty has also been increased through the fact that the supply of visiting teachers is extremely limited. At the time that this is written definite arrangements have been made for placement in the following places: Monmouth County, New Jersey; Bluefield, W. Va.; Kalamazoo, Mich.; Durham, N. C.; Richmond, Va.; Burlington, Vt.; and Warren, O. It is expected that the full complement for the first year, and the ten additional for the second year, will be placed, however in the fall.

In addition, the Public Education Association has also the responsibility of placing and directing visiting teachers in each of the five public schools in New York City with which the Bureau of Children's Guidance, under Section I, is cooperating. Also, the teacher in Monmouth County, as indicated above, is cooperating with the clinic established by the Committee for Mental Hygiene.

Under this section of the program, also, a special piece of work is being financed in Public School 64 in New York City along the same lines employed for several years by the Public Education Association. This is really a grading experiment based on careful psychological tests of the children, and represents fundamentally an attempt to adapt school in-

struction to the needs of the individual pupil. The work has been described at length in various publications issued by the Public Education Association and needs no specific description here. The value of careful consideration and care of the individual in developing the child to the fullest along various lines, and in preventing delinquency through furnishing a satisfactory and constructive outlet for youthful energies has been astonishingly overlooked by educational authorities until comparatively recently.

*Section IV.*—To summarize the undertakings which have been described, we have the following:

*Under Section I:* (1) Provision through scholarships for training psychiatric social workers, probation officers, and visiting teachers at the New York School of Social Work; (2) the Bureau of Children's Guidance, providing training for the types of workers mentioned, together with careful examination and treatment of difficult children from five public schools and other sources.

*Under Section II:* (1) The services of two traveling psychiatric clinics to communities desiring it in connection with their juvenile courts; (2) a special clinic conducted in connection with the Monmouth County Child Welfare Association.

*Under Section III:* (1) The maintenance of visiting teachers in five public schools in New York City cooperating with the Bureau of Children's guidance; (2) the placing of ten visiting teachers per year for a three year period in different communities throughout the country; (3) the special grading experiment in Public School 64.

It is obvious that there are here indicated three somewhat separate and distinct operations which nevertheless have contacts at a number of points. There was necessary a definite coordinating force in order to weld the program into a comprehensive whole. The Commonwealth Fund has therefore established a Joint Committee on Methods of Preventing Delinquency. This Committee at the outset was a purely representative body. Section I is represented in its membership by Mr. Porter R. Lee and Dr. Bernard Glueck; Section II by Dr. Thomas W. Salmon and Dr. V. V. Anderson; Section III by Mr. Howard W. Nudd, director of the Public Education Association; while the Commonwealth Fund is represented by its General Director.

This Committee therefore com-

prised three distinct lines of training and experience, viz.: the social worker, the medically and scientifically trained psychiatrist, and the educator. In this way it was believed that the different points of view and attitudes of approach of these three Sections could be welded into an effective unit. It was intended, however, that the membership of the Committee should be increased to include other persons of experience in the delinquency field. The Committee has proceeded slowly in this regard. It has recently elected to membership Professor Henry L. Morrison, of the University of Chicago, and expects to add several additional members in the fall.

### Coordinating Forces

The purpose of this Committee may be considered to be threefold. In the first place it has served as a coordinating influence in securing the joint operation of the three Sections as a comprehensive whole. Secondly, it has been the intention of the Committee to make a thorough-going study of the work done under the program as well as of other activities along the line of prevention of delinquency. Thirdly, it hopes to publish from time to time accounts of the work and of results achieved in such a way as to point out the possibilities of development. It hopes also to serve as a general bureau of information and clearing house regarding the many efforts in the delinquency field being conducted under the direction of American Social workers.

In order to carry out these last two purposes, the Committee engaged as its executive director in March, Mr. Arthur W. Towne, formerly general secretary of the Brooklyn Society for the Prevention of Cruelty to Children. On May 1 the Committee opened offices at 52 Vanderbilt Ave., New York City, and Mr. Towne is actively at work developing the program. The staff at the present time consists of Mr. Towne and Miss Mabel Ellis, formerly of the National Child Labor Committee, as a special investigator. It will be increased from time to time as the necessities of the work demand.

In order to carry out the purposes of the Joint Committee arrangements are being made to have uniform record forms employed by the various psychiatric clinics, and also by all the visiting teachers employed under the program. Careful analysis of the work done will be made and it is intended to publish a brief bulletin at regu-

lar intervals regarding the various phases of the work. This bulletin and other publications, magazine articles, etc., will be written so far as possible in a simple and non-technical manner in the hope that they may be read and understood by the interested lay public and not, as is often the case with such documents, be merely scholarly and technical treatises to adorn book shelves without ever being consulted.

The chief activities of the program are as described above. From time to time, however, it is expected that various extensions and additions may be made either directly under the program or indirectly connected with it. During the current year special appropriations have been made to the Judge Baker Foundation in Boston for the support of Dr. Healy's work with delinquents, to the New York Probation and Protective Association for a psychiatric clinic for girls, and also for the establishment of a special training school for high grade moron girls in connection with the Manhattan Trade School of New York. This last work has not yet been begun.

The program proper has been adopted for a period of five years. As to whether or not it will continue, either in the present or in a modified form at the expiration of that period, will depend upon various circumstances, such as the effectiveness of the results secured and the conditions existing in the field at the end of the time.

In conclusion, I should like to emphasize again the fact, that in adopting this plan of work, the Commonwealth Fund is not laboring under the delusion that any such effort will revolutionize the world. No pretense is made that it comprises a complete undertaking for the prevention of delinquency. It is simply one of many efforts organized in the hope that it may, by developing certain relatively neglected lines of work, do something of value toward the solution of a very difficult problem. It would be ungrateful for any representative of the Commonwealth Fund to omit in any description of this work an acknowledgment of the hearty interest and cooperation which has been received at all times from the representatives of the operating agencies which, after all, are responsible for the conduct of the work. The devotion and wholeheartedness with which everyone concerned has thrown himself or herself into the making of this undertaking a success has been a source of great gratification.

# Hospital and School for Tuberculous Children

By F. E. HARRINGTON, M.D., LL.D., COMMISSIONER OF PUBLIC HEALTH AND DIRECTOR OF HYGIENE, MINNEAPOLIS, AND WALTER E. LIST, M.D., SUPERINTENDENT, MINNEAPOLIS GENERAL HOSPITAL, MINNEAPOLIS.

**I**N 1912 George R. and Frederick W. Lyman decided to the city of Minneapolis a tract of land containing 78,525 square feet on which stood the Lyman homestead, a spacious, old-fashioned house equipped with all modern improvements. In the rear of this building was another residence, smaller in size but modern in appointments. This donation to the city was made for the operation of a children's hospital and became the pediatric branch of the City Hospital. Some remodeling was done and the much overcrowded children's wards of the City Hospital were transferred to the new institution.

The board of charities and corrections, an executive board of the city

and 50 feet in width for that portion extending to the front and rear wing lines. On the north entrance a cement drive from the street has been constructed for ambulance service. The boiler room and power house are located some 65 feet in the rear of the building connected therewith by tunnel and accessible for coal deposits and ash removal.

The entire grounds have been landscaped and are naturally beautified by large shade trees; cement walks have been constructed. The building stands two stories above the ground floor. It is built of cement brick with cement cornices and trimmings. Being open on all sides it is about 80 feet from the nearest build-

public health and director of hygiene brought about a joint agreement between the board of public welfare directing the division of public health and the division of hospitals, and the board of education directing the department of hygiene. This agreement was to the effect that Lymanhurst was to be opened as an open air school for the education and care of children of school age with active lesions of tuberculosis.

The problem of childhood tuberculosis had been a subject of study and it developed that something over 120 children were at one time being carried on the records of the communicable disease section of the division of public health as active tuberculous

A day school and observation hospital combined in Lymanhurst in Minneapolis

of Minneapolis having charge and jurisdiction over hospitals, in 1917 moved the hospital building to the rear of the lot beside the smaller residence and began the building named "Lymanhurst"; which was completed April 1, 1921 at a cost of \$265,000; it became the pediatric hospital branch of the general hospital system of the city.

This modern hospital building faces east and stands back seventy feet from the property line, giving large grass plots with numerous trees in the foreground. The building is 205 feet long and is constructed on the central administration plan with north and south wings, the wings being 37 feet from front to rear and the main building 67 feet in depth

ing, excepting the power house, and adequate ventilation and light are provided.

At the time the building was turned over by the committee in charge of construction to the department of public welfare as completed and ready for occupancy, it was found impossible to man the building properly because of the shortage of nurses and because of the absence of adequate housing facilities for nurses' home. The building was designed as an eighty-six bed children's hospital. It was not possible to obtain sufficient nurses to serve an institution of that size.

In anticipation of the completion of the building and with a realization of conditions existing with relation to the nursing force the commissioner of

cases. Many of them were too sick to attend school and required hospital or sanatorium care. There was under construction at this time on the grounds of the Hennepin County Tuberculosis Sanatorium at Glen Lake a sixty-bed children's hospital so the application of the idea to Lymanhurst was restricted to children who were able to attend school but who because of their infection were potentially a danger to other children and who under the state law would not be permitted to attend the regular schools of the city. The building is especially adapted to this character of work, is modern in every particular and is arranged as follows:

In the central or administration section on the ground floor are the school

Five of the pupil-patients at Lymanhurst receiving their sun lamp treatment.

All pupils at Lymanhurst retire to their cots after luncheon where they sleep until 2:30 before returning to the classroom.

cloakrooms and a modern, fully equipped x-ray outfit including dark room and technician's office. In this section of the building is located an automatic, electrically controlled elevator. On the main or entrance floor of the central section are the waiting room, director's office, supervisor's office, school principal's office, admitting desk and telephone switchboard with information clerk and a retiring room which has been assigned to the teachers of the school. This room is completely equipped including lavatory, shower and toilet.

On the second floor of the administration section are located the school nurse's hygiene room, the general physician's examining room, the dressing room and alpine lamp treatment room with two large wards facing east and opening on to a large sleeping porch, each room equipped with toilet facilities.

The roof of the administration section is on the same plane with the roof of the wings, is flat, reached by the electric elevator with possibilities of development as a roof sun bath treatment and playground. In the south wing opening on three sides permitting thorough ventilation are sunlight exposure and natural illumination. On the ground floor are located the shower room with dressing rooms capable of accommodating thirteen children at one time, three large dining rooms with serving room and kitchen equipment with all modern hospital dietary apparatus and ventilated by forced electrical ventilators.

On the main or entrance floor of this wing are the classrooms in conjunction with which are a kindergarten room, book and stationery storage and a toilet room each for boys and

girls. The main classroom is about 75 by 70 feet, open on the east and west exposures with a smaller room designated as an enclosed porch open on three sides and facing south with two smaller study or recitation rooms on the east and west exposures between the main classroom and the enclosed porch classroom. On the second floor of the same wing with approximately the same arrangement are the cot rooms, (excepting the enclosed porch which is being used as an additional classroom), in which children are given their one-hour rest period. These rooms are also supplied with proper toilet facilities for boys and girls.

The two front rooms of the central section on this floor and the sleeping porch are also used as cot spaces. Classrooms on both floors are equipped with portable desks and blackboards and can accommodate 125 pupils.

All of the equipment for school purposes is furnished by the board of education. The cot rooms are equipped with a portable folding cot with pillow and slip, sheets and two large, double all-wool eight-pound blankets.

On the north wing on the ground floor are the storerooms for provisions and a large cold storage refrigerator, the shipping room with entrance at the rear, the laboratory, locker and toilet room for employees, diet rooms for personnel both staff and employees, and an isolation room with an outside entrance with toilet and diet kitchen connected for the care of suspected communicable diseases until their removal to the isolation hospital.

On the first or main floor of this wing to which leads the ambulance entrance, as previously described, are

five wards and three physical examination rooms, the former being used as overflow cot rooms and the latter accommodating the activities of the out-patient dispensary service. All persons use the north or ambulance entrance which brings them directly into the dispensary quarters. On the second floor of this wing are located four lateral wards and one large end ward corresponding to the enclosed porch classrooms at the south end of the building. The two wards facing west with the porch ward accommodate twenty beds, and two wards facing east are used for the nurses' room and the patients' reception room. Adequate toilet facilities are provided in this section as well as diet kitchens and property lockers.

In the basement or cellar of the building is the large autoclave sterilizer, storerooms, elevator, engine and refrigerating plant supplying refrigeration for cold storage and other refrigerators throughout the building. all drinking fountains located in each wing on each floor, and for the manufacture of ice for the hospital consumption. Hot water is supplied from the boiler building and steam heat throughout the entire building. The central section is cut off from either wing by a series of vestibule doors with small stairway leading from the vestibules on either wing between the first and second floors. The main stairway is in the central section of the building, leading from basement floor to the roof beside the elevator shaft.

The entire building is of fireproof construction; all floors are cement block and the walls to a height of five feet on the ground floor are plastered with a cement plaster. All partitions are hollow tile plastered and partitions between wards are clear

glass panelled, virtually throwing each wing into a single ward. Lighting facilities are adequate, the lights being controlled from a central switchbox on each floor and wall switches in each ward or room.

The tintings of the walls are of a neutral color, pleasing to the eye, bright enough to be non-light absorbing, easily cleaned, and harmonize with the finish of the woodwork which is mahogany throughout the central section, and mahogany doors with white door and window frames throughout the wings.

All equipment, upkeep and operating expenses other than the furnishing especially designed for the school work are included in the operating and equipment budget of the hospital section of the department of public welfare. The director of hygiene and commissioner of public health jointly with the superintendent of hospitals operate and supervise Lymanhurst with a personnel consisting of a principal, four teachers, a hygiene nurse furnished by the board of education, a supervising nurse who is in immediate charge, three graduate nurses and two undergraduate nurses, a laboratory technician in charge of the laboratory and x-ray departments, a clerk, a telephone operator and information clerk, together with cooks, maids, orderlies, janitors and the proper engineering force. The building, of course, is under active operation twenty-four hours each day.

More immediately associated with the director of hygiene and commissioner of health is a staff of twenty specialists including a otorhinolaryngologist, cardiologist, orthopedist, ophthalmologist, anatomist, hematologist, neurologist, pediatricist, gastroenterologist, roentgenologist, dermatologist, bacteriologist, and specialists

in thyroid disorders and general tuberculosis. This is a volunteer staff and supervises directly all physical examinations and treatments. It is made possible to obtain the services of men of their character and standing because of the unusual offerings for the study of children.

The Lymanhurst School has been established by the board of education as a regular open air opportunity school. The course of study and curriculum embraces all grades exclusive of kindergarten and high school, although high school grades can be taught and will be taught should occasion arise. At the present time all grades from the first to the eighth inclusive are taught at Lymanhurst. Children maintain their standing with the grades of the other schools and can enter or leave Lymanhurst at any period of the school year without detriment to their scholastic standing and this condition of affairs actually does exist. Children are admitted to Lymanhurst and discharged from Lymanhurst at any time during the school year as occasion demands.

Any child who has been definitely diagnosed as actively infected with tuberculosis, even though not definitely an open case, is admitted to Lymanhurst upon the certificate and report of the attending physician or clinic. Children showing signs or symptoms suspicious of tuberculosis infection are examined in the outpatient service which service is restricted to children of school age suspiciously tuberculous. Von Pirquet tests are applied and x-ray plates are made of each child and a confirmatory or definite diagnosis admits the child to Lymanhurst School. Only children who are able to attend the regular school sessions are ad-

mitted. Children unable because of their physical condition to travel to and from school at the regular school hours of 8:45 to 3:15 are referred for admission to the County Sanatorium at Glen Lake. No child once diagnosed is permitted to attend the regular schools of the city and if able must under the compulsory education law of Minnesota attend Lymanhurst. The carfare to and from school for all children traveling on the street cars is paid by the board of education. There are no other methods of transportation provided.

Once a child is admitted to Lymanhurst as a student a routine physical examination is made by the staff both as a coordinating diagnosis and as a matter of study. With full consent of the parents each specialist makes a research study of the child and periodically these findings are compiled into a symposium report. The child is under constant supervision and any conditions arising of interest are reported to the chief of staff and further examinations or studies are made; or, when advisable either from the standpoint of the physical condition of the child or for more intensive observation, children are placed in the ward for a limited period. If after careful observation as a ward patient the child becomes a candidate for sanatorium treatment an application is made and the child transferred to the County Sanatorium at Glen Lake. Upon improvement, however, the child is returned to the day school attendance. Under direction of the staff such treatment as may be indicated is instituted for all children requiring treatment.

Sun lamp treatment in a room equipped with two Hanovia quartz lamps, able to treat six children at one time, is given and all children in

A ward at Lymanhurst.

The Lymanhurst kitchen

the school are given shower baths twice weekly. Diet is carefully supervised and the preparation of food is under the immediate supervision of the supervising nurse.

The daily program at Lymanhurst is as follows:

Children arrive and are admitted and at 8:45 are given a light diet

As rapidly as children are found to have approached a reasonable norm their case is studied by the entire staff and, if advisable, the child is returned to the school of the district in which he lives.

All classroom and sleeping room periods are conducted with open windows, the children and teachers being

ing a temperature as nearly 45 degrees F. as possible.

With the close of the first year of Lymanhurst the records show that there have been admitted to the school 199 children, and discharged therefrom sixty-five children. Since the opening of the out-patient dispensary service on January 24, 1922, 222 chil-

The temperature in the Lymanhurst school rooms is about forty-five degrees which explains the Eskimo costumes.

consisting usually of a cereal or gruel with milk, and in cold weather hot milk or cocoa. Classes convene at 9:00 and continue until 11:00. The recess period is between 11:00 and 11:30 and children are again given a light diet during the recess period before returning to the classroom. At 12:30 the children pass through the toilet and wash rooms to the dining rooms where a full meal is served. This meal consists of a soup, a meat, vegetables, a properly selected green salad, bread and butter, milk, (no tea or coffee) and a dessert. From the dining rooms the children proceed immediately to their cots where they sleep until 2.30. From 2.30 until 3.15 class is again held. At 3:15 the children are dismissed, again receiving a light diet.

The school curriculum is so arranged that daily between the hours of 9:00 and 12:30 an entire class is excused from recitation or study and it is during these hours that the children are subjected to examinations, bathing, sun lamp treatment and weighing. Temperatures are taken daily of all children during the last forty-five minute period.

The records of Lymanhurst are voluminous, each member of the staff making a record of the findings of the examination conducted by him, and these records are bound and become material for study and research.

supplied with Eskimo suits comprising heavy felt lumbermen's boots, bloomers and reefer coats with hoods made of heavy, long fiber, all wool material. These the children wear in class as well as on their cots. Although fresh air is desirable, too low a temperature is not advantageous, so with the steam heating plant in operation the windows are opened sufficiently to produce a constant change of air but with the idea of maintain-

dren have been examined, and since the opening of the observation wards thirty-one children have been admitted and nineteen children discharged. Out of the nineteen children discharged, five went to the Glen Lake Sanatorium.

Lymanhurst fits into the scheme of tuberculosis prevention as an intermediary between the normal child and the child needing institutional hospitalization.

## The Recreation Congress

**T**HE program of the meeting of the Playground and Recreation Association of America presented at the Recreation Congress in Washington, D. C., October 9 and 10 was extremely varied and of the greatest interest as indicating the coast-to-coast activity of this association and the success of community effort, both urban and rural, in achieving facilities for play for the whole people. Play is a re-creative thing and is indulged in spontaneously by the young of every species.

Financing, planning, administering, and legislating for recreation were handled by such authorities as Harold O. Berg of the Cleveland Recreation Council; Lee Hanmer of the Russell Sage Foundation; J. B. Nash,

superintendent of recreation, Oakland, Calif.; and George B. Ford, Newton, Mass. The social side of play, the psychology of recreation, and the recreational use of parks were discussed from the standpoint of the public. Institutional programs were discussed by Charles R. Johnson, secretary of the New York State Board of Charities, and recreation in industry by A. H. Wyman of the Carnegie Steel Company.

The sectional meetings were particularly valuable in the specific problems considered. The figures given out on the year's progress are sufficient indication that the work of the Recreational Association is far-reaching and permanent and of benefit to the nation.

# Greater Efficiency in Health Work in Schools\*

By WILLIAM A. HOWE, M.D., STATE MEDICAL INSPECTOR OF SCHOOLS, ALBANY, NEW YORK.

IN MOST communities there is an appreciable need of greater efficiency in health work in schools. Though substantial progress has been made in many sections, especially in cities and large villages, the work in general is not properly organized, is insufficiently financed, and is far less efficient than it should be considering its admitted importance and its great opportunity for the physical and mental betterment of school children. In an effort to bring out some suggestions for improvement of these conditions, consideration will be given in this article to such school health activities as have resulted from the enforcement of the Medical Inspection Law in New York, which it has been my privilege to administer during the past seven years, under the direction of the State Commissioner of Education.

School authorities should more deeply appreciate the need and value of better health work in schools. One of the most potent factors responsible for the slow growth of health work in schools in many sections, is the failure of school authorities to appreciate its real importance and to give to it proper support. Most school people are more interested in other phases of education than in that of health. They regard health education and health training as a minor and not as a major educational function. There are, of course, many exceptions to this rule but in the main it is far more difficult to sell a program of health to educational administrators than to other people. I regard it, therefore, as primarily essential to accomplish greater efficiency, that school authorities should take a deeper interest in health work in schools and should give to it their enthusiastic support.

Better financial support must be given to the work by trustees, boards of education, and all educational authorities.

With few exceptions the personnel for health work in schools is insufficient and the salaries paid are not commensurate with the services expected or rendered. For instance, in New York State more than seven hundred thousand children, thirty-five thousand teachers and more than ten thousand school districts come under

the provisions of the medical inspection law that was passed by the Legislature of 1913. No funds were appropriated for its administration during its first year, while only five thousand was available for its second year of enforcement. During the first three years the State Medical Inspector of Schools had only a stenographer to assist him. Five years after the enactment of the law a state supervising nurse was appointed. We now have after nine years a staff of seven people, including two stenographers. This staff is inadequate to do justice to the work, and nearly all of them are poorly paid.

## Better Financial Support

Only four of our cities employ full time school medical inspectors. The largest salary paid to any of these four is \$3,400 by the city of Albany, the smallest \$2,000 by Lockport. Many of our school medical inspectors are devoting half time to the service, for which they receive from \$400 to \$1,500 for the school year. The average salary paid to one-half time school medical inspectors in ten of our fifty-six cities is \$1,099.50. Some of these cities have nearly one hundred thousand population. In this group are some of the best qualified physicians we have in the state.

If we are to expect efficient services from physicians we must be willing to pay them enough to interest them in the work. Much of the inefficiency of health work in schools has been due to inadequate compensation to examining physicians. In too many instances the cheapest and not the best local physician gets "the job" of school physician. The school medical inspector is chosen, not because of his qualifications or his interest in the work, but to save a few dollars for the district. This is the fault of both the physicians and the trustees or boards of education. Neither should be a party to a plan that is sure to beget inefficiency and justly to invite criticism of the medical profession. It is essential that school people should stand for the best of medical services and for reasonable compensation for the same. Some headway in this matter is being made in New York State.

The efficiency of any system of school medical inspection is largely determined by the efficiency of its administration. There should be no con-

fusion or doubt in the minds of school authorities as to the placement or responsibility of the administration of health activities carried on in the schools. This confusion or doubt unfortunately does exist in many parts of the country, and even among school people. It should not be forgotten that divided responsibility of administration leads to confusion, invites misunderstandings, lessens interest, increases expense, and materially diminishes efficiency. School people should insist that all activities, mental and physical, carried on in the schools should be under the direction of school authorities. It will not be found practical nor conducive to good administration for one department to attempt to administer activities that are carried on in fields under the control of another department. School health service is fundamentally and logically an educational problem of training teachers and pupils in applied hygiene and in practical sanitation. The physical examination of teachers and pupils and the correction of defects found will be but a minor part of the service when the full educational program of school health service becomes operative. Its ultimate success will be measured not so much in terms of corrective work as at present as in the maintenance of mental and physical health of teachers and of pupils. It also involves school policy, school organization, and school administration. It is a program of keeping well and not one of getting well. It deals with mental and physical health or growth rather than with disease. It is but an integral part of any modern educational system in which many activities must of necessity unite in its proper organization and efficient administration. To be most successful every unit of its organization and administration must articulate with every other educational unit in the completed program. It must of necessity be administered as a part of and not as a part from the educational system in which it operates. It must be administered from within and not from without.

No system of school medical inspection can hope to attain a high degree of efficiency without proper internal and external cooperation. All health agencies within the school, instructional, correctional, or otherwise should be so organized and articulated

\*Delivered before the New Jersey State Teachers Association, Ocean City, N. J., July 11, 1922.

in a department of health education, under the direction of the school medical inspector, that each may be of assistance to all others in the program. This has been done with much success in several cities in New York. The school, the home, physicians, dentists, hospitals, and all local agencies must be brought into closer and more effective cooperation in health work in schools. Emphasis should be placed on the school as the logical community center for health instruction and health direction. To this health center parents should be encouraged to look for guidance in matters pertaining to the mental and physical development of their children. They must be familiar with and in sympathy with the health educational program of the school. They must feel that they are a part of the system and realize that next to the home the school has the greatest concern for the welfare of their children. When such a cooperative relation can be established and maintained between the home and the school far greater efficiency in health work will speedily follow. The health teachings and influences of the school will then permeate the home and influence the entire community for better health conditions. Public sentiment will then support school authorities in demanding more efficient health supervision of the children of the community and far greater progress will be made. It is also essential that cooperating agencies from without should be careful not to confuse the activities of cooperation with the duties of administration. When this mistake is made, as so often happens, many well intentioned agencies really defeat the purpose for which their activities are intended. To prevent such an occurrence, it should be clearly borne in mind, that while several agencies may and should cooperate to accomplish a definite purpose in a special field, there should be but one administrative head responsible for the efficient correlation of all such cooperating agencies.

It is essential for the success of any system of school health service, that proper medical direction should be provided. There is too much of a tendency in some sections and by some people, to depreciate the value and necessity of medical direction and to eliminate the physician, either in part or in full, from the program of health work in schools. This strikes at the foundation of knowledge on which must of necessity be constructed any practical and lasting system of health service in schools. The physicians

must guide this health work in schools, just as they do in matters pertaining to health in our daily lives. Physicians, in general, but school physicians in particular, should take a greater interest in health conditions in schools. They should more fully acquaint themselves with modern methods in the early recognition, prevention, and correction of physical defects among teachers and pupils. They should appreciate that bad school building conditions often impair the mental or physical health of either teacher or pupils and materially lessen their efficiency. The school physician should be as much the logical leader or teacher of health in the schools in his community, as he is among the people of his clientele. He might even be qualified by school authorities as a health teacher and the state pay in part for his services. This would dignify the position of school medical inspector, recognize his services as a state function, make him a member of the teaching staff of the schools he serves, insure to him better compensation, and make his tenure of office far more certain. In such an educational capacity he could do much throughout the year to interest local physicians, dentists, hospitals, teachers, parents, civic and other organizations in practical health work in schools. He would become in fact—that for which his training should qualify him—the school health director of his community.

There is great need for more better educated and better trained nurses who, under the direction of school medical inspectors can do far more than at present to instruct and to train teachers and pupils in the construction and maintenance of health. It is a deplorable fact that comparatively few of our early school nurses had more than two years in high school. Notwithstanding this educational deficiency they have done much to accomplish practical results in school medical inspection, especially in the follow-up work. If the nurse can succeed as she has with such a limited education and training, how much greater would be her success when better prepared to do health work in schools. It is encouraging to note that a higher percentage of the better educated women are entering the nursing profession today and that the educational standards for this work are being gradually increased. In New York state no nurse will be able to qualify as a health teacher after 1924 and receive a state quota unless she is a high school graduate and presents definite evidence of prac-

tical training in the work. The Board of Regents has established qualifications by which registered nurses may become health teachers. Districts that employ a nurse thus qualified receive a state quota toward her salary. Nearly all former school nurses in New York have so qualified and are now employed and known as health teachers. It is essential, therefore, that the health nurse should possess higher educational qualifications and be better trained to accomplish in a more satisfactory manner the special or instructional duties to be required of her. It is also essential that we should have enough health teachers to do the work well. Unless conditions are highly favorable no health teacher should be expected to look after more than 1,500 children. In New York there are today but few large villages with one thousand school children in which a full time health teacher is not employed. About forty health teachers are devoting their full time to health work in rural schools. The school nursing force has increased from eighty in 1915 to about 275 in 1922 exclusive of New York, Buffalo, and Rochester. In the rural as well as in the city school the health teacher is a necessity to get practical results in school health service. It should be made mandatory to employ at least one health teacher in every rural supervisory district, or its equivalent, in the state and to require that the state shall pay a liberal subsidy toward her salary. The health teacher should occupy to the school physician the same relation that the nurse does in the sickroom to the attending physician. By this plan more health teachers and fewer physicians would be able to accomplish a far greater amount of work and in a better manner.

The mere physical examination of school children avails but little unless proper attention can be given to the correction of the physical defects found. Far too many school medical inspection systems are deficient in their attention to the follow-up corrective work. This could be remedied in many instances by apportioning to corrective service a definite amount of funds available for health work in schools. It is not advisable to use all of the money available for physical examination purposes and allow the more important part of the service to be neglected as is done in so many instances. Our cities and large villages are far more efficient in corrective work than are the rural districts. For instance, last year 53 per cent of all physical defects found were cor-

rected or treated in cities and large villages, while only 27 per cent received such attention in the rural schools. This difference in corrective work is a fair comparative index of the health work that is being done in cities and large villages and in rural districts. The situation is no doubt much the same elsewhere and the causes are not unlike those in New York. Rural people, as a class are not as yet as interested in health matters as are people in the larger centers. Fewer physicians are available, and school nurses or health teachers are the exception. Hospital and dispensary services are not so accessible and in many instances the expense of hospitalization is prohibitive. Again, the unit of administration is so small in the rural district, that it is far more difficult to reach it, or at least to influence it to do better health work. To remedy this unfortunate condition in the rural school, the larger and better equipped centers must extend their facilities for corrective service to the less favored sections. A closer and more effective system of cooperation must be established between the cities and large villages and rural districts not only in corrective work, but in all health work in schools. Material progress is being made in this direction in New York. Should these several suggestions be put into effect, far greater efficiency in corrective work would soon be accomplished. More attention could then be given to the far more important problem of the prevention of the many physical and mental disabilities that are so needlessly common among our school children.

Insufficient attention is being given in many communities to matters pertaining to lighting, heating, ventilating, seating and cleaning of school buildings and to the sanitary condition of school grounds. Many of us have failed to appreciate the close etiological relation existing between school building conditions and the health and physical fitness of teachers and of pupils. Many of the acquired physical defects of children as well as much of the inefficiency of teachers are due to existing causes within the buildings in which teachers and pupils are housed. More attention should be given to this phase of our health work in schools, especially in old buildings, as we can not expect to accomplish satisfactory results, either mentally or physically, in buildings that are insanitary and unfit for the housing of children. In the construction of new buildings provision should always be made for

one or more suitable rooms for a school health center, in which should be assembled and closely articulated the activities of the school medical inspector, the school nurse, the physical director and all others doing health work in the schools.

A model or normal plan of health education and health training should be conducted in every institution in which men and women are trained to become teachers. For seven years this has been recommended in New York state. It took three years to induce one state normal school to give some attention to health education and health training. Today all of the ten normal schools and one state college for teachers in New York are doing something along this line. The work, however, is not standardized and differs in many respects in the various institutions. Eleven different plans are being followed in eleven different institutions. While a decided gain has been made in four years there is an urgent need for standardization and for simplification of the work. Every normal school should establish and maintain an efficient department of health education and health training. Inasmuch as nearly all of the pupil teachers are young women, and as medical guidance is essential for successful health service, a woman physician should direct such a department. To assist her should be a nurse, a physical director, and such other experts as may be required. There is no more practical or effective way in which to teach and train prospective teachers than to give to them a practical personal demonstration of what is really meant by school medical inspection or health service. Physical as well as mental qualifications should be demanded for admission to normal schools. Scholastic credit should be given for health attainments as well as for mental improvement, and physical fitness and a working knowledge of personal health, should be required for graduation. Teachers in the service should be taught and trained much in the same manner by those in charge of the work either locally or through the State Department of Education. Present and prospective teachers must be trained to observe deviations from physical fitness and, when found, they should know how to advise the pupil to receive proper attention.

When a child first enters school his mental and physical training should become a regular part of his education. In other words, mental and physical training should begin together

and go together throughout the school life of the child. On his admission to school he should be given a thorough physical and mental examination to detect if possible any defect that might interfere with his mental or physical progress. He should be given a physical and mental rating on the basis of conditions found. His parents should be urged to be present when these examinations are made. These ratings should be reported to his parents, who should be urged to give such attention as is needed or is possible to improve the condition of the child. The school report sent to parents each month should indicate the physical and mental condition of the child, as well as its physical and mental progress. When his physical condition improves he should be credited with the same, and in same manner as with increased efficiency in any other subject. Such a plan would prove a great stimulation to parents to keep their children in a normal physical and mental condition and would exert a tremendous educational influence on the efficiency of school medical inspection. The instruction and training in practical hygiene and sanitation should begin in the kindergarten and continue through the high school. It should be reduced to its simplest terms in subject matter taught and in training given. To be most effective it must be made interesting to children, easily understood by them, and of such a character that they can easily utilize it in the formation and development of good health habits. It is far better to teach less and to have it clearly understood and better applied to health achievements than to teach more that is poorly understood and poorly applied to the formation of health habits. It should apply to every child. It should include daily health inspection of each pupil and should be under the direction of a teacher trained in the purposes of school health service. It should be so interwoven with the daily curriculum that it may be given with no disturbance but as a means of stimulation to the mental training of the pupils. Systematic attention should be given to the correction of defects found, and special emphasis should be placed on keeping well. Its purposes should be to keep every child well, physically and mentally, and to insure to every teacher and to every pupil conditions conducive to health. Every community should be expected to do its best to contribute to the success of the program for educational efficiency in school health service.

From the viewpoint of health our curricula are overloaded and the school day is abnormally long. This is particularly true and most harmful in the lower or grammar school grades. Many pupils do not have more than two study periods in school during the week and are obliged to do nearly all of their work at home.

Something is radically wrong with a school system that requires young children to take an armful of books home to study at night. Honor children in the sixth grade are known who have to study three hours or more at home to prepare their recitations for the next day. This is wrong and it is important to see that it is

rectified. The school day should be of sufficient length for children to begin at a reasonable hour and to get through when school closes. With such a plan children would not only be in better physical condition but would make equally as rapid mental progress. Also, many children are sent to school too young. In most instances they would be just as far advanced with grade work at twelve or thirteen were they to start school at six rather than at five. In brief, let us have a school day and a course of study for children that will enable them to do a reasonable amount of work and then quit until the next school day.

should also take into account this seasonal fluctuation. Intensive nutritional work carried on in the late winter and spring month has often been decidedly discouraging because of this factor.

The "Pelidisi" system is considered briefly. Its use in America has proved of rather doubtful value.

Finally, the basic difference between retardation and defective nutrition must be kept continually in mind in assessing weight to age and weight to height.

## Value of Nutritional Index

THE use of height and weight data as an index of nutritional condition has in recent years undergone great enlargement but comparatively little development. Some doubt has arisen as to the deviation that should be permitted from the existing norms before pronouncing any child to be undernourished or retarded, and as to reliability of weight and height as primary indices of a child's condition.

Realizing this need the New York Association for Improving the Condition of the Poor has issued a pamphlet on Height and Weight as an Index of Nutrition. The subject matter was prepared by the New York Nutrition Council with two objects in view. First, to provide brief instructions for nutrition workers as to the proper methods of recording and interpreting findings. Second, to summarize the recent research findings regarding the growth of children. Several points brought out in the treatment of the second problem are worthy of brief mention in this place.

For one thing it is illogical to expect children of Italian parents living in a congested city quarter to conform to the Burk-Boas norms which are based largely on children of English, German, and Scandinavian stock or to the Wood norms which are based on the children of well-to-do native stock. The formulation of standards based on a cosmopolitan group will not aid in this difficulty but will serve only to obscure the variations that exist between urban and rural and different racial and social groups. These variations are essential if any refinement is to be attained in the use of height

and weight indices. The A. I. C. P. is now tabulating the heights and weights of 3,500 Italian children living in a thickly populated district of New York City. The need for further studies of this nature is great.

Measurements based on different set of children at different ages is fallacious in that the younger age groups contain many physically unfit who die off before the higher age groups are reached. This results in a depression of the norms for the lower ages. The desirable procedure is obviously to take repeated measurements of a group throughout the period of childhood. This method has been used in a few cases but more extensive studies in conjunction with the group method mentioned above are much needed.

The present more or less arbitrary procedure of regarding all children seven per cent or more underweight for height as undernourished is another phase of the problem that needs more study. The most satisfactory measure of the zone of variation is the mean square deviation for each class interval. Previous studies have all indicated that this measure increases with age in respect to the average weight for both age and height. The indications from this method are that the shorter and younger children may be far more than seven per cent under weight without being characterized as dangerously undernourished.

Again it has been shown that during August, September, October, and November boys made 55.3 per cent and girls made 59.8 per cent of the total gains made during the year. Complete tables for different groups

## A. R. A. to Feed Millions of Russian Children

Three million children will be fed in the Southern Ukraine this winter by the American Relief Administration according to announcement by Walter Lyman Brown, director. The continuation of the work on this scale has been made possible largely through the additional contribution of \$1,250,000 from the American Jewish joint distribution committee.

Epidemics are particularly severe in this area, thousands of cases of cholera being reported in a single city. This area is fighting by an inoculation campaign for some 10,000,000 people throughout all Russia and by a sanitary offensive which includes purification of local supplies, cleaning cities, and keeping hospitals and other institutions well stocked. The work in the Ukraine is at present under Colonel William R. Grove, assisted by Dr. Boris Bofen, who will continue to direct it next year.

## Red Cross Roll Call

The Annual Roll Call of the American Red Cross, in which its membership is renewed from year to year, takes place in the period between Armistice Day, November 11, and Thanksgiving Day. This is the only appeal that the National Organization makes during the year; and is for the purpose of maintaining its membership at such a point as will enable it to perform those duties which are placed upon it by Congress.

## St. Louis Recreation Program

THAT the physical and recreational welfare of an urban people depends largely on community efforts to supply an outlet for pent up energies is coming to be an axiom and in late years municipal governments recognizing this fact have established playgrounds, swimming pools, golf courses, tennis courts, and community centers for its citizens.

So important does St. Louis consider the recreation of its residents that it maintains a division of parks and recreation within its department of public welfare for the planning of athletic contests and the maintenance of playgrounds, parks, and community centers. Approximately \$200,000 was spent during the fiscal year ending April 1, 1921 for maintenance of such activities and over four million persons participated.

Baseball, the most popular game, has grown in attendance from 400,000 in 1914-15 to one million participating in 1921 and was maintained at a cost to the department of \$6,962.88, being a per capita cost of \$0.0069. Soccer attendance increased from 190,000 in 1914-15 to 600,000 in 1921 with a maintenance cost of \$2,054.20, per capita cost of \$0.0034; golf was participated in during the year by 164,036 at a cost to the department of \$18,719.09 or a per capita cost of \$0.114; tennis with 218,710 participants cost the department \$12,299.05 or \$0.056 per participant.

The four public baths and four swimming pools had an attendance during the season of 898,106, the total maintenance cost being \$92,418.48.

Besides these major sports, the Municipal Athletic Association conducted contests in swimming, track, field sports, basketball, field hockey, amateur boxing, rowing, bicycling, and horseshoe pitching. The thirty-two playgrounds served 1,812,707 children during the year at a cost of \$67,151.16. The thirteen Community Centers were attended by 270,685 at a total maintenance of \$16,665.73. The automobile tourist camp from July 15 to November 10 accommodated 1,336 tourists. Shower baths and good toilet facilities were erected for their comfort and double camp stoves built.

The city also cooperated with the St. Louis Chapter of the American Red Cross in maintaining a camp for anemic children recommended by various charitable organizations.

A step forward in food sanitation was the passing of an ordinance placing the operation of refreshment

stands in parks under this division. Cleaner stands and better food resulted from this change, the revenue reverting to the municipality.

St. Louis' recreation problem is that of every large city,—the facilities not keeping step with the demand. "Less than ten years ago our parks and playgrounds afforded ample opportunity for play and recreation to those interested," states Rodowe H. Abeken, superintendent of recreation. "In the last three years

## The Subject of Dietetics

THE dietitians as a special group date their existence only five years back, but their importance as a health organization and as a subsidiary body to therapeutic organizations is sufficiently attested by the range of topics covered at the fifth annual meeting of the American Dietetic Association held October 16-19 in Washington, D. C. The administration of dieto-therapy requires as careful checking and observation for its effects as for its initiation. It is not surprising, therefore, to see increasingly high standards of training imposed upon dietitians, or to observe that their fifth national meeting was addressed by such authorities on nutrition as Drs. Mary S. Rose, Alfred Hess, E. V. McCollum, Wm. S. McCann, L. H. Newburg, Elliot P. Joslin, and Walter Cannon.

The proper discharge of the dietitian's responsibilities is no routine measure. In the case of children, as so well advocated by Dr. Ruth Wheeler, the nutritional program spells health and normal development. The racial factors of diet and resultant predispositions to disease were well exemplified in the report of findings in China by Emma Gunther of Teachers' College, Columbia University, and in the Italian dietary survey reported by Gertrude G. Mudge, chairman, Committee of Italian Dietary Survey. It is becoming necessary to study not only the patient and his economic and sociological background but food idiosyncrasies and certain mental attitudes as affecting the dietaries that may be defective require of the food expert a well rounded preparation.

The following officers were elected for the ensuing year: President, Octavia Hall, Peter Bent Brigham Hospital, Boston; first vice-president,

the interest and enthusiasm have grown to such an extent that all our recreational facilities are overtaxed at least 250 per cent."

"To reach every child in the community St. Louis should maintain seventy playgrounds instead of only thirty-two; more swimming pools are needed; a Municipal golf course on property adjoining O'Fallon Park as well as one in Carondelet Park should be laid out; tennis courts provided with lights for night play should be built to relieve the congestion on the present courts; the number of baseball diamonds is totally inadequate."

Mrs. Hallie Corsette, U. S. Public Health Service, Washington, D. C.; second vice-president, Miss Effie Raitt, Washington University, St. Louis; secretary, Miss Breta Luther, Children's Hospital, Boston; treasurer, Miss Anna Boller, Chicago.

## Street Sanitarians Meet in Chicago

The International Association of Street Sanitation Officials at their annual meeting in Chicago, October 9, discussed many topics of vital interest to health. A round table discussion was held on methods of garbage, rubbish, and ash collection. Incinerating reduction of garbage was discussed by Clifton H. Fisk of St. Louis and Mat Miser, superintendent of streets and sewers, Philadelphia, Pa.

The difficulties of certain traffic conditions as affecting street cleaning were fully canvassed. The concensus of opinion seemed to be that this hindrance can best be met through police power and official cooperation. The question of newspaper cooperation and help from civic bodies and from school children in promoting help among citizens themselves in the matter of municipal house-keeping was held to be an important one. Automotive equipment was recommended in the interests of economy and efficiency in street cleaning either for rubbish or snow.

Wages, the use of equipment, and the suitability of uniforms, were likewise discussed and an interesting session was devoted to department organizations for recreation. The newly elected officers included W. J. Galligan, Chicago, president, and Theodore Eichorn, Geary, Pa., treasurer.

## A High School Social Center

THE advantages of operating a social center in a high school have been set forth in the high school social center maintained by La Salle-Peru-Oglesby, Ill. Through this joint arrangement a maximum of use is secured from the equipment, for the building is in use from early morning until late at night. During the morning and early afternoon the gymnasium, swimming pool, and dressing rooms are used by high school students, and at noon high school students use the reception room, reading and game rooms. From

lished one of the great zinc companies in that region. In order that the center might remain as a permanent structure in the community and to assure public interest in its welfare, a condition of its donation was that it should be supported by public taxation.

The social center is housed in a two-story and basement brick building adjacent to the township high school and connected with it by a covered passage. At the time of the erection of the new building, the gymnasium on the ground floor of

Adjoining the athletic field, which is used mainly by men and older boys, and which has been named in honor of its donor, Mr. Matthiessen, is the playground for the use of the smaller boys and girls. The playground is simply equipped and includes a baseball diamond, and basketball and volleyball courts.

The high school social center serves the three towns in the township. They are typical industrial centers, many of the inhabitants being foreigners. As a result of the demand for unskilled labor, boys and girls of-

The Social Center Recreation building adjoins the high school and is used by students and public alike.

3:30 p. m. to 10 or 12 p. m. the building is open to the public. The high school and social center both use the same athletic grounds.

A second economical advantage is the fact that members of the social center staff can also serve as high school teachers. The director teaches economics and sociology in the high school and together with his assistant has charge of the high school boys' gymnasium classes. The instructor for women and girls teaches the high school girls' gymnasium classes. Another important advantage is the fact that the older high school boys and girls can be used as Social Center attendants. About fifteen students are employed at 20 cents an hour. This amount often enables students to remain in school who otherwise would not be able to do so.

The social center of the Tri-Cities was the gift of the late F. W. Matthiessen who in the early days estab-

the high school building was converted into an auditorium and the high school structure in part remodelled and completely renovated. The cost of maintaining the center is approximately \$9,000 a year which sum is paid from the high school educational funds. Though no attempt has been made to make the center self-supporting, activities in large part pay for themselves and rental fees collected for the use of the party room and gymnasium cover practically all incidental expenses.

In connection with the social center building there is a large athletic field of eleven acres. The field includes a five-lap cinder track, a baseball diamond, football field, and jumping and vaulting pits. On the south side of the field is a concrete grand-stand with a seating capacity of five hundred. It is equipped with a drinking fountain and men's and women's toilets. Nearby are two tennis courts.

ten leave school as soon as the law allows. Recreation for this group is especially imperative. Until the establishment of the Social Center no attempt had been made by the public to provide recreation for either adults or children and commercial recreation of unsupervised character flourished.

The social center has had cooperation of the health department and the associated charities of the three cities. The health department has been of use in solving the problems of sanitation in regard to swimming pools and has examined swimmers to detect weak hearts and communicable disease.

A series of home nursing classes was held at the social center under the direction of trained nurses. First aid classes under the direction of men from the Mine Rescue Station and the Hygienic Institute (Health Department) were also held. Frequent lectures are given on health and social hygiene topics.

**C**OMplete oral hygiene as practised by nurses and other attendants is not only recognized as good administration, but is a necessary precautionary measure adopted by medical directors, superintendents and superintendents of nurses in the safeguarding of patients.

Interest in sanitary, healthy mouths of hospital personnel grows steadily. The subject will receive even more attention in the future.

Colgate's Ribbon Dental Cream does all that a dentifrice can do in cleansing the teeth and maintaining oral hygiene.

Colgate's Dental Powder holds a high position among those of the dental profession who prefer a dentifrice in powder form. As with Ribbon Dental Cream, it is based on the same fine precipitated chalk and pure soap.

*A copy of "A Babe in the House" booklet and a generous supply of samples will be sent to registered nurses postpaid on request.*

## Examination of Food Handlers

FROM a public health point of view the main concern in regard to the physical condition of food handlers is not that they be free from physical defect but that they be free from diseases which they may easily communicate during the course of their duties. Tests, therefore, should be based on the discovery and elimination of those suffering from tuberculosis and venereal diseases and those who prove to be typhoid or diphtheria carriers or in the incipient stages of these diseases.

Such a sanitary examination would include only the chest examination for tuberculosis, the skin for contagious disease, nose and throat for diphtheria, a routine blood test for typhoid, and in males, the examination of external organs for venereal diseases. This routine examination would provide the minimum safeguards against infection by food.

The many reports of tuberculosis and venereal disease among cooks and waiters in the city of Newark, N. J., led to the establishment of special clinics by the Division of Food and Drugs which were transferred to the Division of Tuberculosis of the Department of Health. Authority for this procedure was contained in New Jersey State Sanitary Code, Regulation 37 which states that "any waiter, cook or other person employed in any hotel, restaurant, boarding house, or other place where cooked food is offered for sale, who handles or prepares food, may be required to submit to a physical examination by a medical inspector of any local board of health or of the State Department of Health for the purpose of ascertaining whether or not he is affected by any communicable disease, whenever in the judgment of the health officer such examination may be necessary."

The procedure in the clinic is as follows: The Division of Food and Drugs arranges for the examination of the food handlers and issues a food handler's card, good for a period of six months after the approval by the Division of Tuberculosis. This latter Division conducts the whole examination with the aid of clinic physicians detailed from the Division of Contagious Diseases and the Bureau of Venereal Disease. No card is issued without the requisite report from the clinics.

All food handlers were brought under the surveillance of the department by a city ordinance passed in

1918 which provided that all food handlers with the exception of those handling meats or foods ordinarily peeled or cooked before eating should present a certificate from a physician stating that such person was free from tuberculosis or any contagious disease.

The result of the Newark examinations is interesting. Since August 1920, 11,059 examinations have been made by the Department of Health. Among this number, not a single typhoid or diphtheria carrier was located. In regard to tuberculosis, 9 per 1,000 were found in 1920 and 1921 and only 6 per 1,000 in 1922. Among the 11,059 examinations only 37 cases of venereal disease were found. Only 54 skin eruptions were found, 42 the first year, twelve the

second year and none the third year. The decrease in all these diseases is accounted for by the fact that the knowledge that such physical examination had to be undergone kept many diseased from applying. Vaccination was also required of all individuals.

Coincident with the opening of the Atlanta, Ga., public schools a dental clinic was established under the direction of Dr. John R. Kennedy, city health officer, and the school superintendent. Portable dental chairs are used. Days are set aside for examination of the children's teeth in respective schools. Recommendations are to be made to the family dentist as to any dental defects, and if the parents are financially unable to pay, the work will be performed free by the school dentist, according to the school board's plan.

## Public Health in China

BY FRANK L. MELENY, PEKING UNION MEDICAL COLLEGE, PEKING, CHINA.

IN ALL countries, the history of governmental interest in public health has been preceded by a period of private initiative. During the past twelve months there has been more general activity of a private nature in China than ever before in a similar period and it should not be long before it can be reported that there are definite government activities in this field.

This statement, however, is made guardedly because there have been so many spasmodic movements which have been started with the best intention but which have come to naught that it is not possible to say just how far the present movements will carry the country into a real, live stable, permanent and progressive public health policy. For instance, recent political events have interfered with the growth of the work of the health department so hopefully established by the defacto Southern Government in Canton. Similarly, political events of the past few months have materially affected the original plans of the National Health Association whose organization was reported last spring. Perhaps the most significant step has been the filling of chairs of hygiene in the three foremost medical schools in the country, namely, in Peking, Changsha and Tsinanfu. Scarcely of less significance has been the organization of city health association in Shanghai, Nanking,

Changsha, Tientsin, and Peking.

The most common specific health work being carried on in the various cities is along the lines of maternal and infant welfare. Under the auspices of the Council on Health Education, with headquarters in Shanghai, health institutes for this work have been conducted in Nanking, Changsha, Kuling, and Fengchow. An institute in educational hygiene, very similar to the one being conducted for the first time by Harvard this summer, was given in September by the Peking Union Medical College. Also, for the first time in the educational history of China, a section on school hygiene will be conducted at the national educational conference held in Tsinanfu, Shantung, in July.

In 1919 the Central Institute for Epidemic Prevention was created with the balance of a national appropriation to combat plague. This year, after the original money had been expended, the government authorized an annual budget of \$120,000 from customs funds to continue the work under the auspices of the new Central Anti-plague Prevention Bureau. This is really a misnomer, for it is expected that the chief work of this Bureau will be to establish a government institution which will supply all kinds of serums and vaccines to the country to aid in the fight against disease.

## A flexible shoe for your flexible foot

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank* and *natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, nappiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a chance to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

## Interdependence of Life Medical Directors

An insurance medical director of some prominence is quoted in *The National Underwriter* to the effect that life insurance medical directors are much more influenced by the methods being pursued by other companies than formerly.

He asserts that the independence of action and thought that characterized the handling of the life insurance medical department in the past is less in evidence now. He attributes the change to the experimenting in substandard cases that is being done by so many life companies at this time.

In giving his views he said:

Life insurance medical men are being disturbed every day by what competing companies are doing. Here is what happens. A case is presented to me for examination. I find a defect sufficiently serious to warrant me in turning the applicant down. Accordingly, I decline to issue a policy.

A little later I learn that another company has granted the applicant insurance without rating him up. This sets me to wondering. I try to see why the company issued a standard policy. Knowing that the applicant should not have a standard policy I come to the conclusion that the company is doing experimenting along substandard lines, and then try to follow the other medical director's line of thought. I attempted to see why he would take the case, and what he expects to develop. I am influenced by the case, because when a similar one is presented, I am perhaps more inclined to take it on some basis than I was before. I am following the experimenters.

Medical requirements are more liberal than formerly. Companies are studying impaired risks with the idea of writing as many as possible. The medical director who followed the old rule-of-thumb methods is going out of favor. Today life insurance companies are insisting that their medical directors experiment and find out what they can do with certain types of impairment. All of this means that life insurance medical men can no longer pursue a strictly independent course. They must take cognizance of what other companies are doing. The effort to do this is upsetting individual standards, and is bringing a liberality of attitude that would have been unthinkable, even ten or fifteen years ago.

## Measles, a Serious and Widespread Disease

"Long association with measles has bred a contempt for it but its dangers are none the less severe," states Dr. W. C. Rucker, Surgeon of the United States Public Health Service, in a bulletin of the service. About

10,000 American children died of the disease in 1920. This does not include a large number who died of bronchial pneumonia, many juvenile cases of which were caused by measles. Approximately 60 per cent of all deaths from bronchial pneumonia occur in children under five years of age, a time of life when measles is most likely to occur. But the story of the ravages of this disease is not complete, Dr. Rucker continues, without mention of the large number of cases of tuberculosis which follow it. Less frequently inflammation of the ear or the eye may be left behind as a mark of a visitation of this common disease. From a public health standpoint, then, measles is a disease of prime importance.

Measles, in common with other diseases of childhood, has come to be looked upon as an unavoidable accompaniment of youth. Each autumn when school opens there is an increase of measles and as the season progresses they gradually increase and winter frequently sees the disease spreading in epidemic form.

At present, the disease is distributed over the entire habitable globe, from Iceland on the north to Tierra del Fuego on the south, states Dr. Rucker. It occurs most often and most severely in the colder months, probably because at such times people are more closely crowded together under more insanitary conditions. When introduced among a people who have never suffered from it before its ravages are frightful, as in the case of the inhabitants of certain of the Fiji Islands, who, upon being exposed, fell ill and died by thousands, so that it is estimated that 20,000 deaths occurred in four months.

In 1917 three states had a death rate from this disease of more than forty per 100,000, and several cities had even a higher rate. The death rate for measles for the registration area of the United States in the period 1911 to 1919 has ranged from 3.9 per 100,000 in 1919 to 14.3 in 1917.

The death rate among those attacked varies from one-half to 1 to 35 per cent. If it is estimated that the death rate is 1 per cent, and the number of deaths from measles in the United States in the year 1920 was 10,000, then it would follow that in that year at least 1,000,000 children suffered from this disease. When it is considered that perhaps 30 per cent of these children were of school age, and that the disease occurs most often in the months of school attendance, then it will be seen that ap-

proximately 300,000 children were kept from school from six weeks to two months on account of measles. Leaving out of consideration the death and suffering produced in this way, this is a serious economic loss.

It is thus seen that measles is many times a very severe disease, one which cannot be dealt with lightly, one to which we should not expose our children. The longer one can put off having measles the better, because the younger the child is when it has the disease, the more likely it is to die, and the more likely it is to suffer severe effects from it even if it does not die. The most fatal period is from two to five years of age.

## China Health Posters

Attractively colored educational posters are being used in China by the Council on Health Education under the direction of Dr. W. W. Peter, secretary.

On the reverse of the posters are instructions, printed both in Chinese and English. On the poster on teeth

are set forth the proper method of brushing the teeth, the substitution of salt in boiled water when paste or powder is not available, the factors favoring, and the factors inhibiting decay. It also states that "China has too few dentists. This is another reason for taking good care of one's teeth."

Another poster carries directions for thorough mastication, for the avoidance of constipation, and for the use of special chopsticks or spoon and never one's individual utensils when serving food.

## Metatarsalgia and Callouses Caused by Weakened Transverse Arch

This condition is recognized by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe.

These conditions, Doctor, are quickly relieved and permanently corrected by the use of

### *Dr Scholl's* *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in

every community who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

Important pamphlet, "*Foot Weakness and Correction for the Physician*," mailed upon request.

## Sex Education in Favor in U. S. Schools

That the majority of educators favor a conservative school program of sex education was revealed by a questionnaire sent out by the Cincinnati Social Hygiene Society to one thousand deans of schools of education, principals of normal schools, superintendents of education, physicians and nurses. Approximately 498 replies were received.

The courses in which such instruction is given include social hygiene, anatomy, embryology, ethics, literature, and sociology. The total number of students reached in the grades is 6,770; in high schools, 146,981; in normal schools, 83,433; in colleges, 92,108. The attitude of both parents and students has been found to be largely favorable to some form of sex education. The principal methods of presenting the material to the students is by assignment for recitation with an informal talk, or lecture followed by private talks with individuals.

## Lethargic Encephalitis Epidemic in Poland

A comparatively mild epidemic of lethargic encephalitis occurred in Poland in 1917. Following this no outbreak of epidemic proportions appeared until 1920 when, during the latter part of February and the first of March, at a time when the influenza epidemic of that year was on the wane, the disease again appeared in unusual quantity. Reporting was made compulsory on March 11 and questionnaires sent to the physicians in the country. In spite of the errors and omissions in the statistics compiled from these sources, they are believed to represent with a fair degree of accuracy the salient features of the epidemic. A report was made to the Office International d'Hygiène Publique by Dr. Chodzko, delegate to Poland, and published in the July issue of the *Bulletin Mensuel*.

The peak of the epidemic was in Warsaw during the month of April. The spread of the disease was to the south and east and in these districts the greatest severity was experienced in the late spring and summer months. Several cases were reported as late as November and a total of 1,374 cases and 264 deaths were recorded. Twenty-six per cent of the cases among males were in the age period from thirty to thirty-nine while among females the age groups from fifteen to nineteen and from twenty to twenty-nine each contained

nearly 27 per cent of the total number of cases among females. No cases were reported among males below five or over fifty-nine years of age while the female cases ranged from two years of age to seventy-two.

The clinical aspect of the epidemic is dealt with at some length in the report which states that the cases observed divided themselves into three categories, each having a rather distinct group of symptoms. The native doctors expressed themselves negatively on the question of a possible relationship with the preceding influenza epidemic. No constant time interval was found between the attacks of influenza and encephalitis in the history of patients that had contracted both diseases.

## Germany Enacts Venereal Disease Law

The German venereal disease law, advocated by many social-hygienists in that country, which has been under discussion for some time, has now passed through the Reichstag. This law, reports the Social Hygiene Bulletin, provides for continuity of treatment and makes an offender who spreads venereal disease, knowing or suspecting that he or she is in an infectious state, liable to three years imprisonment. Treatment is to be free for those who cannot afford to pay, and the patients are obliged to submit to treatment for as long as the medical authorities consider necessary.

A further provision concerning penalties for exposure of persons to disease will protect wet nurses and the babies put out to nurse. Other clauses provide penalties for the quack and for the medical practitioner who undertake treatment by correspondence. They also prohibit offensive and misleading advertisements.

Obligations are imposed on the doctor who undertakes to cure venereal disease; he must give each patient instruction as to the nature of the disease, and in the case of patients under age, must inform their parents or guardians. Lastly he must explain the new law and its penalties to the patient. The German Society for Combating Venereal Disease approves the law.

## The Relation of Physical Defects to Sickness

A statistical study by Selwyn D. Collins of morbidity among 3,786 Missouri school children appeared in *The Public Health Reports*, September 8,

1922, under the above title. This study was an attempt to discover what relation if any existed between certain physical defects common to children of school age and the number of days of absence from school.

The multiplicity of combinations of defects that will be encountered in a study of this nature necessitates condensation to avoid an unwieldy detailed classification. In this analysis seven groups were employed. The basis of comparison was the percentage of the total school days lost by the various groups. This percentage of school days lost is given for all the groups studied by absence on account of sickness and by absence on account of causes other than sickness.

It was shown that children with no defects lost less time from school on account of sickness than those with defects. Those with enlarged or diseased tonsils were absent more than those having no recorded defects. Children having other defects associated with enlarged or diseased adenoids or tonsils were absent more than those with enlarged or diseased tonsils only. Decayed teeth appeared to have little or no effect on the time lost and defective vision failed to show any consistent influence.

Absence from causes other than sickness varied much like the absence from sickness; the group with no defects showed the lowest percentage of days lost.

A permanent mental health clinic has been opened in Wilkes-Barre, Pa., under the direction of Dr. Horace V. Pike of the Danville State Hospital.

# No Growth Without Vitamines

The Bio-Chemical Laboratory of the University of Cambridge recently conducted an exhaustive investigation to determine whether the vitamines known to be present in the raw materials from which VIROL is manufactured were present in their active state in the manufactured VIROL as sold to the public. This report which fully proves the presence of the vitamines in VIROL will be sent to any medical man on application.

## Advantages of VIROL

It contains the vitamines.

It is a well balanced food.

It is easily absorbed in the most delicate conditions.

VIROL exercises a remarkable influence on growth and development. It is a food of great value for expectant and nursing mothers, in anæmia, malnutrition, and all wasting conditions.

## Bread Standard and Baking

THE Joint Committee on Definitions and Standards has recommended the adoption of standards for breads for the guidance of Federal and State officials in enforcing food laws, according to a statement issued by Dr. W. W. Skinner, chairman of the Joint Committee.

The standards recommended do not become effective under the Federal Food and Drugs Act, a bulletin of the United State Department of Agriculture explains, until they have been formally adopted and published as a food inspection decision by the Secretary of Agriculture, nor do they become effective under State food laws until formally adopted or acted upon by the authorized State representatives. The standards are announced by the committee in advance of their formal adoption, so that no hardships may be worked upon the industries affected. The text of the recommendations follow:

"Bread is the sound product made by baking dough consisting of a leavened or unleavened mixture of ground grain or other clean, sound, edible farinaceous substance, with potable water, and with or without the addition of other edible substances. In the United States the name 'bread,' unqualified, is understood to mean wheat bread, white bread.

"Wheat bread, white bread dough is the dough consisting of a leavened and kneaded mixture of flour, potable water, edible fat or oil, sugar or other fermentable carbohy-

drate substance, salt and yeast, with or without the addition of milk or a milk product, of diastatic or proteolytic ferments, and of such limited amounts of unobjectionable salts as serve solely as yeast nutrients and with or without the substitution of not more than 3 per cent of the flour ingredient by some other edible farinaceous substance.

"Wheat bread, white bread is the bread obtained by baking wheat bread dough in the form of a loaf or of rolls or other units smaller than a loaf. It contains, one hour or more after baking, not more than 38 per cent of moisture, as determined upon the entire loaf or other unit.

"Milk bread is the bread obtained by baking a wheat bread dough in which not less than one-third of the water ingredients has been replaced by milk or its equivalent. It conforms to the moisture limitation for wheat bread.

"Rye bread is the bread obtained by baking a dough which differs from wheat bread dough in that not less than one-third of the flour ingredient has been replaced by rye flour. It conforms to the moisture limitation for wheat bread.

"Raisin bread is the bread obtained by baking wheat bread dough, to which have been added sound raisins in quantity equivalent to at least three ounces for each pound of the baked product and which may contain proportions of sweetening and shortening ingredients greater than those

The Experimental mill which has been installed in the laboratories of the Department of Agriculture in Washington where experiments with wheat and other grains are being conducted. The experimental mill turns out the flour which is used in the department's bakery where its actual quality is determined by its conversion into bread under standardized conditions.

commonly used in wheat bread dough.

"Brown bread, Boston brown bread is a bread made from rye and corn meals, with or without flour, whole wheat flour, rye flour, with molasses, and in which chemical leavening agents, with or without sour milk, are commonly substituted for yeast. In some localities the name brown bread is used to designate a bread obtained by baking a dough which differs from wheat bread dough in that a portion of the flour ingredient has been replaced by whole wheat flour."

### Birthrate Declines in U. S.

The birth rate is declining and the death rate increasing, according to statistics made public today by the Census Bureau covering the first quarter of the year. The birth rate in the states from which comparative figures were available showed an average of 23.3 for each thousand of population in the first three months of 1922, against 25.3 in 1921, while the mortality average in the registration area in the first quarter this year was 13.7 against 12.6 in the same period last year. North Carolina, with 29.2, reported the highest birth rate for the three months this year, and the State of Washington, with 16.5, the lowest. The District of Columbia had the highest mortality rate, with 17.6, and Wyoming the lowest, with 9.6.

Electric ovens, part of the experimental equipment of the Department of Agriculture.

# Just completed!

## *Three separate investigations by competent authorities on the results of yeast therapy*

What happens to the living yeast cells in the alimentary tract?

Has fresh yeast any marked tendency toward laxative action?

What is its effect on the leucocyte count?

Investigations into these and other phases of yeast therapy have recently been completed.

It is now definitely established that fresh yeast *is absorbed in part by the system, and produces a marked increase in leucocytes, thus aiding in the correction of suppurated conditions.*

It has also been demonstrated that yeast, after passing into the intestine, *softens and increases the bulk of the feces by absorption of moisture, and produces a distinct laxative effect.*

Detailed reports of this work will be given the medical profession in the near future.

There is still data to be gathered on the inter-relation of yeast and alimentary bacteria; and further investigations, sponsored by the Fleischmann Company, are now in progress.

*A new authoritative book:* written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and the therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing THE FLEISCHMANN COMPANY, Dept. Y-11, 701 Washington Street, New York, N. Y.

### *New brochure on yeast therapy sent on physician's request*

## Sanitary Meat Market in Alabama

Meat market in Edgewater, Ala., showing proper screening which prevents contamination from flies and handling.

## Tuberculosis: Tracing Sources of Infection

Three types of tubercle bacilli, known respectively as the human, the bovine, and the avian are now definitely recognized in the causation of tuberculosis, but their distribution among the various species of animals is not easily demarked, for the human type is not confined to man, or even to mammals, nor the avian type to birds, while the bovine type occurs in a large variety of animals, not excepting man himself. The distinction between the types, questions of susceptibility and of natural resistance to the several types, and opportunity for infection by the specific type therefore assume the highest importance in combating tuberculosis.

The rôle of the three types of tubercle bacille in human and animal tuberculosis, the stability of types, and relative virulence under varying conditions and changing hosts constitute the material of a lecture recently delivered by Dr. Louis Cobbett before the Royal Institute of Public Health in London, and reported in *The Lancet* of May 20, 1922. It is a curious fact that the rabbit is almost the only mammal which shows any great susceptibility to infection by the avian type of bacillus. Cobbett divides the mammals into two groups according to susceptibility to infection with the human type of tubercle bacillus. "To infection with the bovine type all mammals are probably more or less susceptible, and no animal—with the single and doubtful exception of man—is known to be more susceptible to infection with the human type than

with the bovine type. A certain group of animals, including man, dog, guinea-pig, monkey, and other foreign mammals, are susceptible to natural infection with both mammalian types of tubercle bacillus. The other group contains practically all our domesticated mammals, except the dog." The donkey is the most resistant to tuberculosis of all our domesticated mammals. Among birds, swans, geese, and ducks are resistant.

Foreign animals kept in captivity seem to be infected at least as often with the human as with the bovine type of bacillus. With the dog especially, opportunity for infection with one type of tubercle bacillus is more important for consideration than are the differences of virulence for the animals of the types themselves. The rat and the mouse are mentioned as a possible means of spreading infection of the avian type from one poultry farm to another. As to the possibility of changing one type to another, Dr. Cobbett does not consider it proved that modification from one type to another occurs, but says that cases of apparent change become less as experimental conditions have been improved. His figures on the relative extent of bovine infection in man are based on the assumption of stability of types. Excessive incidence of bovine tuberculosis has been reported from Scotland. American figures stand between those of England and Scotland. While he was unable from data on hand to give world figures, he was obliged to conclude that there is probably a very considerable difference in the proportion of bovine infection in different countries. From a tabulation of the deaths attributed to tuberculosis of all kinds, about 6.5 per cent are due to bovine bacilli, probably in the majority of cases the infection coming through milk.

## Therapeutic Agency of Elephant and Clown

Keystone View Company, Inc.

The elephant and clown, the trick pony and dog did their bit recently in maintaining the morale of the sick children at the Children's Hospital, Boston, and their antics furnished practical illustration of the therapeutic value of laughter.

## LOESER'S INTRAVENOUS SOLUTIONS

ACCEPTED BY THE COUNCIL

### LOESER'S INTRAVENOUS SOLUTION OF MERCURY OXYCYANIDE, 8 Mgs.

A sterile, stable solution in nonsoluble glass ampoules, 5cc containing 8 mgs. ( $\frac{1}{8}$  grain) of Mercury Oxycyanide

### LOESER'S INTRAVENOUS SOLUTION OF MERCURY OXYCYANIDE, 12 Mgs.

A sterile, stable solution in nonsoluble glass ampoules, 5cc containing 12 mgs. ( $\frac{1}{6}$  grain) of Mercury Oxycyanide

We offer these solutions to the medical profession as a means of carrying on intensive mercurial treatment of syphilis.

The objections to the intramuscular method, lack of uniform absorption, irritation, induration and abscesses, are overcome by the intravenous administration.

The superiority of these solutions of Mercury Oxycyanide over the intravenous administration of the so-called acid salts of mercury, bichloride, biniodide, etc., is due to the fact that they are less apt to cause irritation of the veins, a common fault of most soluble mercury compounds.

Clinical Reports, Reprints, Price List and "The Journal of Intravenous Therapy" sent to any physician on request.

## Management of the Sick Infant

For the first time in the history of American pediatrics a book has been devoted entirely to the treatment and management of the sick infant. It is interesting to see a textbook that does not follow the general outline adopted by textbook writers such as etiology, pathology, symptoms, diagnosis and treatment.

Langley Porter and William E. Carter have succeeded in giving a general view of all diseases of infancy without putting it in a narrow frame. The line of treatment advocated by these two authors is modern and up-to-date. It is evident that the authors have based their views on experience gained in many years of practice. The book constitutes a contribution to pediatrics. It is a volume of value to the practising physician and at the same time is intelligible and of value to nurses and those responsible for the institutional care of sick children.

C. V. Mosby Company, St. Louis, 1922.

## Backwaters of Lethe

"Backwaters of Lethe" by G. A. H. Barton is a delightful little booklet in which the author discourses in a dreamy manner on the various phases of anesthesia. The book has no index, there is no bibliography, nor is the reader met with stern, cold lists of statistics.

The author has sunk into a large arm chair and from its comfortable depths through blue clouds of fragrant pipe smoke narrates to the reader in delightfully unpedantic phrases a surprisingly large number of most practical facts concerning anesthesia.

Paul B. Hoeber, New York, 1922.

## Surgical Nursing by Russell Howard

A series of lectures delivered to the nurses at the London Hospital forms the basis of "Surgical Nursing" by Russell Howard. The book contains in a brief summary the underlying principles of modern surgery and describes these in a manner a nurse can understand and appreciate.

Howard realizes that in order to carry out instructions not only intelligently but with interest the nurse must understand the why and wherefore of these orders. Moreover, there are times when a nurse is forced to act on her own initiative, and in these instances a clear conception of con-

ditions is of course essential. The present edition, the fourth, has been thoroughly revised.

Edward Arnold, London, 1920.

## Protein Therapy and Non-Specific Resistance

Only a few years have elapsed since the attention of students of immunology and practising physicians was directed to the possibility of non-specific reactions in infectious diseases. During these years much scientific thought has been lavished on this subject, and perhaps more unscientific propaganda have been spread. In America two names stand out prominently as leaders of the scientific inquiry into the nature of non-specific resistance,—Jobling and Petersen.

"Protein Therapy and Non-Specific Resistance," by William F. Petersen, represents the results of his work and is a most interesting presentation. To those whose thoughts have failed to penetrate into this mystery Petersen's book will prove valuable; to those practitioners who are ready to use non-specific therapy without regard to underlying principles, Petersen's discussion should be even more valuable.

Macmillan, New York, 1922.

## A Volume on Obstetrical Nursing

The book, "Obstetrical Nursing" by Carolyn Conant Van Blarcom, R.N., contains an enormous amount of information. It has value not only as a textbook for nurses but as a text, or at least a reference work, for physicians as well. The style is very pleasing and the literary quotations from many authors are very interesting. The author possibly overstepped her boundary by including in the book material that properly belongs to a textbook on pediatrics. The pediatric material, however, is well chosen and as a whole, well written.

The Macmillan Co., New York, 1922.

## The Book of Life, Mind and Body

A hodge-podge of scientific fact and pamphleteering is Upton Sinclair's recent book "The Book of Life, Mind and Body." The volume serves to spread on paper all the theories concerning mental and bodily well-being that the author has accumulated in a lifetime.

Just how a man who wrote so effectively in "The Jungle" and "The Brass Check" could turn out "The Book of Life" is a mystery. In "The Jungle" and "The Brass Check," he was at least familiar with the field; but for a layman to write seemingly authoritatively in the medical and public health field leads only to disaster.

The first section, "The Book of the Mind," dabbles with "Mother Eddy's" theories, with spiritualism, and with the accepted psychology. "The Book of the Body" dwells at length on diet, fasting, and vegetarianism as cures of many ills. It would seem that a book dealing with health subjects requires a more dignified treatment than the personal vein which the author employs.

The Macmillan Company, New York, 1921.

## Public Health Agencies in New York

The New York County Chapter, American Red Cross, through its Health Service, announces the publication of a Directory of Health Agencies in New York City.

This directory covers 97 agencies and 12 branches in the five Boroughs. When the local Chapter of the Red Cross first compiled a tentative list of public health agencies in New York County, it was only a 16-page pamphlet. The present directory, revised and enlarged so as to include all the boroughs of the city, contains 44 pages. In addition to the table of contents the directory contains a classification index, there are also a subject index and a personnel index.

New York County Chapter, A. R. C.

## Principles of General Physiology

William Maddock Bayliss has been a leader in physiology for many years. He is one of the most outstanding figures among English physiologists. In the third edition of his book, he has treated general physiology both as a scientific and philosophical subject. It is not a book for the general practitioner but rather is it a reference book for a scientist who wants to be informed on advanced knowledge of physiology.

Among the many other interesting side lines in Bayliss' book in his historic knowledge and the numerous photographs of physiologists of various ages.

Longmans, Green & Company, London, 1920.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

## Labor Problems and Labor Legislation

In "Labor Problems and Labor Legislation," John B. Andrews, secretary of the American Association for Labor Legislation, New York City, has presented a brief summary packed into 135 pages of the historical development and present status of the more important branches of industrial health and welfare. The task would seem to be an impossible one but the author has accomplished it with extraordinary success. The high points in connection with unemployment, wage legislation, hours of labor, industrial safety and sanitation, self-government in industry, social insurance, and the enforcement of labor laws are touched upon with a balance and skill which make it a fascinating introduction to the subject for the open-minded industrialist or social worker and which give it a real value even to the specialist in these fields. One might have desired a trifle more consideration of the problems of industrial tuberculosis and of current tendencies toward industrial democracy but the book as it stands deserves a place on the shelves of every intelligent student of industrial problems. Excellently selected illustrations add to its popular value.

## Sewerage and Sewage Disposal

In 1914-15 Leonard Metcalf and Harrison P. Eddy published "American Sewerage Practice" in three volumes. These books were excellent for general engineering practice, but were not well adapted to ordinary class room use. To meet this class room need they now publish a textbook "Sewerage and Sewage Disposal," which is an abridgment of their three earlier volumes. The greater part of the work of condensation has been done by John M. Goodell, for many years editor of the *Engineering Record*. In the abridgment, changes have been made and new information introduced in order to bring the book thoroughly up to date. The authors state that they "are engineers, not teachers, hence this textbook reflects the engineer's rather than the teacher's view point."

The book opens with a chapter on general features of sewerage and sewage treatment works in which are given definitions as recommended by the American Public Health Association. There are also included in this chapter brief discussions of the influ-

ence of topography and method of disposal on the general sewerage plan. The following two chapters are on quantity of sewage and quantity of storm water. In each of these chapters are illustrative problems with maps showing the application of the principals explained. A chapter on hydraulics of sewers presupposes a knowledge of hydraulics. In this chapter are several diagrams and tables for the rapid solution of the ordinary type problems. This is followed by chapters dealing with appurtenances, investigation, construction, and inspection.

Almost half the book is given over to sewage disposal. There is first a chapter on chemical and biological characteristics of sewage. This is followed by chapters on the different methods of disposal. The chapter on sludge is rather meager. The book ends with a chapter on cost estimating. No attempt is made to give cost data because of the lack of reliability under present conditions. The book is well illustrated.

In the preface the authors state as their purpose "to prepare a book, giving information which they consider desirable for the young student to acquire before taking up work in this field. In this textbook they have fulfilled their purpose and the student or young engineer will find here a book which well meets his needs.—ROSCOE H. SUTIE, Yale University.

McGraw-Hill Book Co., New York, 1921.

## Transformation of the Intestinal Flora

In view of the commercial exploitation, the popular interest, and the scientific investigation aroused by attempts at altering the bacterial flora of the intestinal tract, Leo F. Rettger and Harry S. Cheplin's review of the subject and concise summary of their own experimental investigations is of value.

The greater part of the book is given over to the experimental work of Rettger and his collaborators and to discussion of the results obtained. The latter may be briefly summarized as establishing the fact that it is possible to implant *B. acidophilus*, a normal member of the intestinal flora usually present in small numbers, in the intestinal tract and that the usual mixed or putrefactive flora may be changed to one in which *B. acidophilus* predominates by the simple addition of lactose or dextrin to the food.

The experimental work upon rats and man with *B. bulgaricus* invali-

dates completed the belief that this organism can be implanted in the intestinal tract.

The practical conclusions to be drawn are, first, that it is possible to transform the normal or abnormal putrefactive flora of the intestine into a less variegated one in which *B. acidophilus* predominates. This change may be brought about best by the combination of carbohydrates in small doses with living cultures. Secondly, that the altered flora reverts to the normal mixed type upon the return to a diet which does not contain sufficient amounts of lactose or dextrin. Thirdly, that the use of *B. bulgaricus* for the purpose of transforming the flora appears to be a useless procedure for which there is no experimental support. The preparation of a *B. acidophilus* milk or broth, which shall actually contain viable organisms, is a laboratory procedure which will not easily lend itself to commercial methods.

Yale University Press, New Haven, 1921.

## Meeting Your Child's Problems

Every child is a problem in himself. There are certain questions, however, that can be answered in a general way. Though the book by Miriam Finn Scott by no means answers all the problems that confront parents or teachers, still there are a number of questions that are discussed in a clear cut manner. At times the author uses too many examples to illustrate her point. Most of the illustrations, however, read quite well.

Little, Brown & Company, Boston, 1922.

## Tuberculosis and the Community

Tuberculosis has come to be known as a sociologic problem. Even the laity realizes now that a tuberculous person is not only a problem to himself, but also to the community. So far, however, we have had no monograph dealing with tuberculosis as a communal problem.

The book "Tuberculosis and the Community," by John B. Hawes, 2nd, M.D., therefore, fills a want in medico-sociologic literature. The author discusses, among other things, the question of hospitals and sanatoriums for consumptives; the aftercare of the consumptive; the relation of tuberculosis to the school child, to housing, and to occupation.

STATEMENT OF THE OWNERSHIP, MANAGEMENT,  
CIRCULATION, ETC., REQUIRED BY THE ACT  
OF CONGRESS OF AUGUST 24, 1912,

OF THE NATION'S HEALTH, published monthly at Chicago,  
Illinois, for October 1, 1922.

State of Illinois, }  
County of Cook } ss.

Before me, a Notary Public, in and for the State and county aforesaid, personally appeared Dr. O. F. Ball, who, having been duly sworn according to law, deposes and says that he is the president of The Modern Hospital Publishing Co., Inc., and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher: The Modern Hospital Publishing Co., Inc., Chicago, Illinois.

Editor, Dr. C.-E. A. Winslow, New Haven, Connecticut.

Associate Editor: S. P. Moore, Chicago, Illinois.

Business Manager: James G. Jarrett, Chicago, Ill.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

The Modern Hospital Publishing Co., Inc., Chicago, Ill.; Dr. O. F. Ball, Chicago, Ill.; F. M. Bailey, Chicago, Ill.; James G. Jarrett, Chicago, Ill.; Alfred P. Sloan, New York, N. Y.; James M. Ball, St. Louis, Missouri; N. E. Ball, St. Louis, Missouri.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees, or other security holders.

O. F. BALL, President.

Sworn to and subscribed before me this twenty-second day of September, 1922.

[Seal]

J. P. McDERMOTT, Notary Public.

My commission expires August 9, 1925.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

## FROM THE FIELD

Free medical advice and treatment and use of the recreational facilities of its five story club building are accorded members of the Spanish Society at its center 24 West Sixteenth Street, New York City. The society also maintains a free hospital bed for members. Plans are under way to build a hospital at an estimated cost of \$200,000. A nucleus of \$12,000 has already been raised.

Shoes will be built in the future more along health lines was the consensus of opinion at an open forum of the New York State Retail Shoe Dealers' Association recently in session at Albany. The brogue for men will be popular while high heels on women's shoes are being displaced by the Cuban and Spanish heels which are broader and flatter, the shoe dealers state.

The Toronto Institute of Hygiene is proposing to undertake a special inquiry into the subject of the poisonous action on the workers employing a spray of fumes arising from the volatile substances like turpentine, benzine, or benzol contained in paint mixtures.

A new attempt to establish a permanent safety museum in the United States has been made by Commissioner Clifford B. Connelley of the Pennsylvania Department of Labor and industry. Complete plans for an International "Safety First" exhibit have been laid before the committee in charge of Sesqui-Centennial Exposition to be held in Philadelphia in 1926. It is hoped that a permanent building for housing the international safety exhibit will be built. Commissioner Connelley established a safety exhibit at Carnegie Institute of Technology, Pittsburgh, where he was for many years the Dean of the School of Applied Industries.

The training of health visitors in Scotland is discussed in a general way in a memorandum issued by the Scottish Board of Health. The specialized instruction course is to cover not less than one and a half years and should follow a student's intermediate or secondary school course. It should include elementary anatomy and physiology; general hygiene; personal

and clinical hygiene; public health administration; social science and economics; office work; dietetics and household management. On the practical side not less than two and one-half years are to be spent in hospital or other work of a similar nature.

Detroit has assigned to its department of health from ten to fifteen uniformed policemen as a sanitary squad who are kept continually busy inspecting alleys and yards for the elimination of nuisances. Faulty disposal of garbage is found not only in the poorer districts where lack of facilities encourage uncleanness but is also evident on the best residence streets. The department urges that vacant lots, instead of being regarded as fit repositories for waste, should be converted into playgrounds.

In the past four years largely through the efforts of the Canadian National Committee for Mental Hygiene, provision for the insane and mentally defective has increased to such an extent that Canada stands well up at the head of the nations. The Provinces of Canada have spent \$5,125,000 in the last four years on buildings and equipment for the care of the insane, feeble-minded, and defective.

At the request of Health Commissioner Fronozak of Buffalo, the Division of Vital Statistics of the New York State Department of Health has made a special preliminary report on the infant mortality of Buffalo. This study was also undertaken because of its bearing upon the state-wide campaign for saving the lives of mothers and babies, as inaugurated by the department under the provisions of the Davenport-Moore act, which was passed by the Legislature and approved by Governor Miller last March.

According to this report, as prepared by Dr. Otto R. Eichel, Director of the Division of Vital Statistics, the death rate from preventable causes under one year of age has declined in Buffalo from 140 deaths for each 1,000 births in 1900 to sixty-two in 1919. During the same period the rate from diseases classed as non-preventable has remained virtually stationary.

In this favorable showing the infant mortality of Buffalo corresponds closely to that of New York, which has one of the best records in this respect of any large city in the world. This inquiry into the Buffalo infant mortality involved computing and charting the mortality under one year of age from each cause for each year from 1900 to 1919 for Buffalo, and also for New York City, to make possible comparison with the latter as a standard. This study is intended to be only a first step in a thorough analysis of the mortality of Buffalo for use by the state and local health departments in formulating their programs.

Plans to improve the condition of Indians, with particular regard to health and education, are being worked out by Commissioner Burke of Indian Affairs with the approval of Secretary Fall. An increase in the estimates for the Indian Bureau probably will be asked in the next Indian appropriation bill.

The Polish Minister of Public Instruction has issued a circular to school authorities prescribing in detail measures for the care of school children's health and measures against epidemics and contagious diseases among school children, and directing the establishment of school playgrounds. The minister has also ordered lectures on hygiene for parents and children.

How to reconstruct their devastated lives is the great problem now facing more than four million Jews in Europe outside of Russia according to Dr. Lee K. Frankel, chairman of the special commission sent abroad last June by the American Jewish Relief Committee. "The medical program of the committee is going ahead as fast as funds will allow," stated Dr. Frankel. "The erection and repair of public baths is highly important, particularly in the smaller communities, and I find that close to 250 more baths must be rebuilt. The importance of these baths cannot be over estimated. More x-ray stations must be established as well as special schools for the education and training of nurses. It is most encouraging to note the splendid work of the American doctors connected with the committee, some of whom have been at their posts for more than a year at a time without relief. Several have gone through typhus epidemics."

## CHILDREN'S SHOES

that are  
*Scientifically  
Designed*

MANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed. Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

*One Twenty-Two Hudson Street, New York*

## *Certainty of Quality Promptness of Service*

There is frequently an urgency in the requirements of a Public Health Department, Dispensary, Industrial Hospitals and Surgeons in charge of the health groups, that calls for more than ordinary cooperation on the part of the supply house. Likewise there must be a positive assurance of the quality of each and every item.

With a full appreciation of these conditions the Chemists Supply Co. seek the patronage of these groups. Intelligent service is given on every order; the quality of our product satisfies the most exacting. The various chemicals, vaccines, solutions in ampoules, drug specialties and kindred supplies used daily or in an emergency, are at all times available, in necessary quantities.

*Try us in an emergency—Your satisfaction  
will assure your routine business.*

**CHEMISTS SUPPLY CO., Inc.**  
61 E. Lake St. Chicago

The Harvard School of Public Health, established last year as the result of the endowment received from the Rockefeller Foundation, which will ultimately amount to more than \$2,000,000, opened this fall for the first time. During the first half year Dr. Roger I. Lee, Professor of Hygiene, will serve as Acting Dean of this school in the absence abroad of Dr. David L. Edsall, Dean of the Medical School. The faculty of the school includes Drs. Richard P. Strong, Milton J. Rosenau, Lawrence J. Henderson, George C. Whipple, Cecil K. Drinker, and Prof. Edwin B. Wilson.

The School of Public Health has purchased for its headquarters the Rotch Memorial Building, but probably will not occupy the building until next spring. At present the School of Public Health is housed in the Medical School Buildings.

The new school is the outgrowth and continuation of the school jointly conducted by Harvard and the Massachusetts Institute of Technology since 1913, and will include certain departments, such as those of industrial hygiene and tropical medicine, which hitherto have been a part of the Harvard Medical School. It will be closely associated with the Medical School.

The American Red Cross, at the request of the Interior Department, recently assigned three trained nurses to the Indian Bureau for one year, as the first step in Commissioner Burke's program. In addition, plans for enlarged school facilities to educate 20,000 children of school age not now in school are being worked out. Approximately 6,000 of this number belong to the Navajoe tribe and have never been to school. One nurse will be stationed on the Pine Ridge and Rosebud Reservations in South Dakota; the two others will go to the Southwest, and work among the different Indians in Arizona and New Mexico.

"The Interior Department and the Indian Bureau are giving much attention to health conditions at the several Indian schools and upon the different Indian reservations," says Commissioner Burke, "and the present policy is to try to have at least one hospital on every reservation with a capacity sufficient to care for the sick, and particularly for Indians who are very aged and infirm and without means or homes where they can be comfortably and properly cared for."

Statistics as to child labor in the

United States in 1920 have been published by the Bureau of the Census, under the title "Occupations of Children." In the nine tables of this publication are shown the number and proportion of children gainfully occupied in the United States in each of the divisions and states, in the principal cities, and in specified occupations; and the distribution of these children by age, sex, and population class.

An investigation of the causes of maternal and infant deaths during the past year in Massachusetts will be the first feature of the new program of the division of hygiene of the Massachusetts Department of Public Health. For the purpose of carrying on this work two physicians and a vital statistician have been added to the staff. A supervisor and a staff of five nurses will soon be attached to the division, whose main purpose will be to stimulate prenatal and infant care.

At the suggestion of the Prussian Ministry of Social Welfare the Public Health Academy of Charlottenburg, Germany, has decided to establish courses in social dentistry as supplements to the courses in public health. The course was held from June 12 to July 8. Besides general instruction in public health, the dentists were taught methods of dealing with children of pre-school and school age. Special attention was given to children's diseases connected with defects of the oral cavity. At the East German Academy of Public Health in Breslau a course in social dentistry was given from June 19 to July 1. This course consisted of general and special lectures and seminar work in public health, social medicine, social legislation, social welfare work, and similar subjects of interest to the dentists.

Germany is adopting American psychologic methods in industry writes the Berlin correspondent to *The Journal* of the American Medical Association, and the head committee of the Prussian legislature has adopted unanimously the suggestion of the Minister of Public Welfare that a state institute for the study of labor problems and industrial hygiene be created. By training motormen in accordance with modern scientific principles, the Greater Berlin Street Railway Company effected a saving of 12,000,000 marks for the last fiscal year and also decreased materially the number of accidents. The men

were also trained in one-third the time formerly required.

A study of mercury poisoning by Dr. R. R. Sayers of the United States Bureau of Mines shows poisoning from mercury to be of common occurrence both in the mining and the smelting of this metal, although by far the greater number of cases are found among the employees about the reduction works.

The principal causes of poisoning are poor ventilation and failure to prevent the escape of mercury from furnaces, condensers, and retorts, and uncleanness on the part of the workmen. In addition to these causes there is a wide variation in the susceptibility of different persons. The use of alcohol and tobacco seems to increase both susceptibility and severity of symptoms, while women and children and tuberculous individuals are considered to be most easily affected.

Measures recommended in the report for the prevention of poisoning include the provision of adequate general and exhaust ventilation; of respirators, of one shower bath for every ten employees and one washbasin for every five; individual lockers; lunch rooms; physical examinations of applicants for employment, excluding drinkers, those having tuberculosis or those in poor physical condition, and persons under eighteen years of age; periodic physical examination at least every six months; and instruction to employees as to the dangers of mercurial poisoning and methods of avoiding it. The necessity for strict personal cleanliness and for keeping in good physical condition is emphasized.

The Committee on Public Health of the Massachusetts Medical Society has arranged a program of lectures to be given by specialists before district medical societies of the state. Lee Hamilton, M.D., 164 Longwood Ave., Boston, is in charge of the lecturers.

Twenty-five thousand dollars was allowed Dr. Royal S. Copeland, Commissioner of Health of New York City, by the Board of Estimates to fight diphtheria during the coming year. For the diphtheria bureau Dr. Copeland was allowed five physicians, five nurses, two bacteriologists, two laboratory assistants and eight helpers. The work of the bureau will be to prevent the disease by means of the Schick test and toxin-antitoxin treatment.

# Entangling the Dust Battalions,

# Semdac Liquid Gloss

(A SUPERIOR POLISH)

**E**VEN the rustle of the nurse's uniform—symbol of cleanliness—will stir up the tiny, germ-laden dust particles, for no matter how clean the hospital, the dust legions are there.

The weapons carried by the dust-army are dangerous. Practically all contagious diseases are air borne. The pulmonary diseases such as grippe, pneumonia, tuberculosis as well as the germs causing diph-

theria, are transferred by dust. These dust battalions are harmless when imprisoned in Semdac Liquid Gloss.

Semdac keeps dust from flying by enveloping each dust particle in a film.

Semdac Liquid Gloss cleans and polishes all kinds of finished wood-work, metal, and enameled surfaces. It is entirely odorless, and, therefore not unpleasant to the patients. It is made in the laboratories of the Standard Oil Company (Indiana.)

*For sale by dealers and all agents or agencies of*

A notable step has been taken at Yale University in the appointment of Dr. W. C. Rappleye as Superintendent of the New Haven Hospital, affiliated with the Yale School of Medicine. Dr. Rappleye, it will be remembered, prepared the report of the committee on the training of hospital executives appointed by the Rockefeller Foundation and his appointment guarantees a development of the New Haven Hospital as a social institution on the most broadly conceived lines.

The annual state conference of the Minnesota Catholic Hospital Association will be held at Rochester, Minn., December 5 and 6.

The Illinois State Department of Public Health plans to place a district health superintendent on the program of every teachers' institute scheduled to be held in the state during the remainder of 1922. The object is to obtain the closest possible cooperation of the school authorities in the medical examination of children. A definite method for making practical medical examinations will be presented to the teachers in pamphlet form.

Dr. Marion Dorset, Chief of the Biochemic Division of the Bureau of Animal Industry, Department of Agriculture, will cooperate in an unofficial and consultative capacity with the Anthrax Advisory Committee of the International Labor Office, Geneva, Switzerland. Dr. Dorset has been connected with the Department of Agriculture since 1894 and has held his present office since 1904. The date of convening this committee has been fixed for December 5 at Geneva.

The Illinois State Department of Public Health is initiating a campaign to immunize young children against diphtheria without reference to the Schick test. This procedure is the outcome of a meeting of thirty public health officials which was held at the Pageant of Progress in Chicago, August 2, 1922.

The Life Extension Institute, Inc., during the past year has secured contracts from seven life insurance companies for the annual examination of their policy holders. The Metropolitan Life Insurance Company, in a statistical study of cases examined, found a reduction in mortality of 28 per cent among the policy holders examined by the Institute in 1914 and 1915 and a reduction of 67 per cent

in the mortality of those found to be impaired. The Institute has referred its examinees to family physicians for treatment representing fees amounting to between five and ten millions of dollars.

Plans are nearly completed for turning over as a free gift the common stock of the Institute to several leading universities in order that the control of the Institute will ultimately be in the hands of the trustees of these universities.

A Congress of Hygiene will be held in Strassburg, Alsace-Lorraine, France, in the spring of 1923. Dr. Borrel, professor of hygiene at the University of Strassburg, is organizing the congress and is in charge of the exhibits.

John Ritchie has been employed as part time publicity director for the Massachusetts Tuberculosis League. Mr. Ritchie was for years Health Commissioner of Boston and later editor of the *American Journal of Public Health*.

In an effort to promote industrial understanding the National Personnel Association has appointed committees to conduct inquiries into various fields of industrial relations. F. P. Pitzer, superintendent of employment and service, Equitable Life Assurance Company, has been appointed chairman of the health education committee.

Atlanta, Ga., is establishing an open air school for children whose health might be impaired in indoor class rooms. The school will be part of the public school system.

Laurel, Miss., has been chosen as the site for a health unit by the International Health Board of the Rockefeller Foundation. A five-year program will be started immediately with a view to stamping out malaria. The unit will also serve as a training ground for members of the Rockefeller Foundation preparatory to service in foreign subtropical fields.

Comparing the standards prescribed by state child labor laws with the standards of the federal child labor tax law which was declared unconstitutional May 15, 1922, it is found that the laws of the following thirteen states measure up in all particulars to the standards of the federal law: Alabama, Connecticut, Illinois, Indiana, Kansas, Kentucky, New

York, Ohio, Oklahoma, Oregon, Tennessee, West Virginia, and Wisconsin. Certain other states come fully up to one or more of the standards but fail in regard to others. The states which fall below the federal standards in all respects are Delaware, Mississippi, and Wyoming.

At the annual meeting of the American Occupational Therapy Association held in Atlantic City the following officers were elected: Mr. T. B. Kidner, president; Dr. G. Canby Robinson, Baltimore, vice-president; Mrs. Elenor Clark Slagle, secretary-treasurer. Dr. William R. Dunton, Jr., Baltimore, is chairman of the committee on publicity and publications.

With the cooperation of the U. S. Bureau of Labor Statistics, the International Joint Conference Council of the allied printing industry, representing both employers and employees, has authorized a nationwide health survey of the printing trades. The survey, which it is expected will take two years, includes every phase of the industry bearing directly or indirectly on health, physique, and physical efficiency.

The Housing Division of the Indiana State Board of Health has added to its staff an inspector whose entire time will be given to inspecting and scoring rural homes. It is expected that he will inspect and score five hundred homes in different parts of the state in one year.

The Kansas Division of Water and Sewage is making an extensive investigation to determine the degree and sources of pollution of the Kansas River.

The Massachusetts Legislature has appropriated \$15,000 for use in "extending the activities of the Division of Hygiene in the protection and care of mothers and conservation of the welfare of children." This amount is to be expended during the remaining months of the current year.

During the past year the seventeen workers of the Mothers' Allowance Commission of Canada paid 18,290 visits to 2,660 beneficiaries. Of this number 2,320 were widows, 268 wives of the totally incapacitated; 54 the wives of men presumed to be dead; and 18 foster mothers. The Commission prevented the breaking up of many homes and the scattering of many families.

## A Master Magazine

SIX THOUSAND people located in all parts of the world subscribe for the issues of The MODERN HOSPITAL—six thousand people realize the intrinsic value of each copy. The clinics, hospitals, institutions, and interested hospital workers are finding valuable editorial matter and interesting illustrations in every issue.

You may not be officially connected with or directly interested in a hospital, but prominently evident in all public health and social service organizations is and always will be the influence of the hospital. In this era of rapid development, you will want to keep in touch with the newer ideas as they are presented in each issue of The MODERN HOSPITAL.

Start your subscription now. Have a copy of the magazine sent to you personally each month. The yearly subscription rate is \$3.00.

THE MODERN HOSPITAL PUBLISHING CO.

22 East Ontario Street, CHICAGO

The National Junior Sports League has recently been formed by men prominent in the world of sport for the purpose of promoting clean sport among the boys and girls of this country between the ages of 8 and 18. The league makes the backyard, side street and vacant lot the playground, and the question of equipment is solved in every community. It, however, also plans to work with the physical directors, scoutmasters, Y. M. C. A. physical directors, camp directors and those who are working with boys and girls. If a boy has passed a test in the Boy Scout movement, the Red Cross Society, the Y. M. C. A., schools and similar organizations equivalent to that of the National Junior Sport League, it will not be necessary for him to pass another test.

Six thousand persons in nine Michigan institutions are being cared for by the Michigan Department of Health according to figures given out by Dr. R. M. Olin, commissioner. The department of health began dental work in penal and correctional institutions in May, 1921 and since that time complete dental surveys have been made in ten institutions and department dentists have visited and worked in twelve. During the first year 26,210 operations were performed at a cost of 47 cents each.

A new opportunity for specialized training for nurses at Montefiore Hospital, New York, is reported in *Better Times*. The new training school will lay special emphasis on the preparation of nurses for the care of patients suffering from chronic diseases. Special courses will be given in hydro-therapy, mechano-therapy, electro-therapy, occupational therapy, and tuberculosis nursing. Eight months training at Bellevue Hospital is also included in the course

which lasts two and one-half years and leads to the degree of Registered Nurse.

The *Journal of Physical Chemistry* is to be published under the auspices of the American Chemical Society, the Chemical Society of London, and the Faraday Society of Great Britain. Francis P. Garvan, president of the Chemical Foundation, has guaranteed \$10,000 annually for five years to the publication, it was reported to the council.

According to the agreement between the Rockefeller Foundation and the government of Honduras, a hook-worm disease section and a public health department have been organized in that country. The Foundation will bear 66 per cent of the expense during the first year and 34 per cent during the second, and the Honduras government will assume all expense from the third year on.

A silver loving cup, the gift of an anonymous New Yorker, has again been awarded to the state of Iowa. The cup is awarded yearly to the state whose schools have the highest percentage of total population successfully completing the Modern Health Crusade. The National Tuberculosis Association stated that the Iowa schools had won five out of eleven first prize banners and sixty-eight out of 182 second prize pennants.

Dr. Gleason C. Lake of the U. S. Army Medical Corps arrived recently in Phoenix, Ariz., to conduct a campaign against the Malta fever epidemic which has appeared during the last three weeks in the Salt River Valley. With the outbreak of the epidemic, the state superintendent of health wired the federal authorities for an experienced officer to assist in handling the situation, and Dr. Lake

was given the commission. The appearance of Malta fever in Arizona is regarded as curious. Fifteen cases appeared in a short time, with one fatality. Acting on the theory that milch goats are carriers of the germ, a herd of 500 goats from which Phoenix obtains its supply has been placed under quarantine, and the sale of goat's milk stopped by the city authorities.

The hygiene institute for the University of Leipzig is organizing a German Gesellschaft für Gewerbehygiene. The leading men in the movement are Prof. K. R. Lehmann, director of the hygiene institute at Wurzburg, Dr. Koelsch, and Dr. Laymann of the state department of labor, Dr. Gottstein of the state department of public welfare, and representatives of employers and employed in the various industries.

The International Union against Tuberculosis, which recently held its session in Brussels, has announced that the 1926 meeting will be held in the United States in connection with the sesquicentennial of Philadelphia. The next meeting will be held at Berne, Switzerland, 1924. Dr. Theobald Smith, director of the Rockefeller Foundation animal research laboratory at Princeton, N. J., is president-elect for the American conference.

A permanent school of army hygiene will be established at Aldershot, England, to carry on the lessons in hygiene learned during the war.

The Rural Sanitation Office of the United States Public Health Service reports that there are 203 counties throughout the United States that have a local health service under the administration of whole-time county or district health officers.

## INDUSTRIAL SURGEONS

Yesterday industrial medical work was thought to belong to the young graduate without experience,—a bread-and-butter job, until a private practice was gained.

Today both the industrial executive and the physician and surgeon recognize that intensive training and specialized experience are necessary.

Aznoe's Service, likewise recognizes these conditions and seeks, by discriminating selection to serve intelligently both the industry and the surgeon.

At the present time many thoroughly qualified industrial surgeons are available for this specialized practice.

Let us tell you how Aznoe serves both the industry and the individual.

## Academy of Medicine Contributes to Health

### New York Committee Pioneers in Health Methods for Organized Medical Societies

By E. H. LEWINSKI-CORWIN, PH.D., EXECUTIVE SECRETARY, PUBLIC HEALTH COMMITTEE, NEW YORK ACADEMY OF MEDICINE, NEW YORK CITY.

THE code of medical ethics, adopted in 1847 by the American Medical Association, recognizes physicians as conservators of public health and declares that "it is a delicate and noble task, by the judicious application of public hygiene to prevent disease and lengthen life, and thus to increase the productive industry, and without assuming the office of moral and religious teaching, to aid the civilization of an entire people." Early in its history the New York Academy of Medicine stated in its constitution that one of its four objects was the promotion of public health; and in 1852, following the precept quoted above, it created a standing committee on public health. In 1858 a section on public health and legal medicine was established, which existed until April 26, 1911 when at its own request it was abolished by the Council of the Academy and replaced by a committee on public health. This committee under its present organization is the only organization of its kind in the world.

The academies of medicine of some of the European countries have an official status, obtain means for their maintenance from their respective governments, and are called upon at times by the governments to advise in matters pertaining to public health. Occasionally they undertake, on their own initiative, consideration of some public health problem, but none of the medical bodies abroad or in this

country maintain a sustained interest in current public health problems, as they arise, or consider them from the broad point of view of municipal policy and in the light of accumulated thought and knowledge which comes from a continuous contact with the whole realm of public health.

Aside from the services rendered to the community, the Public Health Committee of the New York Academy of Medicine by its eleven years of work has established a tradition for the Academy, has revealed to the citizenship the practical idealism of the leaders of the medical profession, and has demonstrated the applicability of the objective survey to the domains of public health and administrative and educational medicine.

#### Advisory Body to City Health

The studies of dispensaries and hospitals is an illustration *par excellence* of the application of the method of the detailed objective inquiry which reveals existing conditions and strives by constructive criticism to improve them. Such were the studies of the health unit plan organization of the Health Department, of the contagious disease hospitals of the Department of Health undertaken ten years ago, of the conditions at Quarantine Station, of the Bureaus of Records, laboratories and child hygiene of the Department of Health. Incidentally, I may add that in connection with the study of the last named

bureau, the committee was the first, to my knowledge, to set a standard ratio of physicians and nurses to school population in the work of medical school inspection of children. Of a similar character were the studies of health conditions in the police force of the city, pollution of the harbor, the protection of the Croton watershed, of the value of open air tenement houses, air space in institutions for infants, malnutrition among school children, and of street cleaning during the course of which were collected all available data on the pathogenicity of street dust.

In addition to studies and surveys, the Committee has given to the community its collective opinion on the value of many proposals and such administrative procedures as quarantine of measles, typhoid immunization, reporting of venereal disease cases, reporting of cases of encephalitis lethargica, segregation of mental defectives, tonsil and adenoid operations, control of typhus fever, drug addiction, factory health inspection, oligogenics, popularly known as birth control, certified milk, twilight sleep, the need and character of the state census of population, etc.

The Committee answered every request made on the part of governmental and civic agencies for assistance in ascertaining facts, shaping policy, or aiding them in the discharge of their duties. The municipal Civil Service Commission called fre-

quently on the Committee for advice with regard to the selection of medical examiners, plan and scope of examinations, and bases for rating candidates. The city departments asked for aid in supporting their budget requests and for judgment with regard to the advisability of new or established procedures; the civic organizations are continuously appealing to the Committee for advice whether it be in planning a new experiment or in appraising the value of an established procedure. The committee was called upon to suggest remedies to check the increase in the prevalence of myopia among school children, to prepare standards for physical examination of children between the ages of 14 and 16 working in factories, to express an opinion on the advisability of employing teacher mothers in the schools, to prevent poisonings from wood alcohol, to stimulate the use of "occupational therapy," to aid in the work of codification of the state laws pertaining to child welfare, etc.

During the several epidemics which visited the city during the last decade, the Committee arranged special meetings at the Academy, and in statements issued to the public press dealt with what was known as to the causes of the epidemics and the methods of prevention. In addition to conferences on poliomyelitis and influenza, two regular meetings of the Academy, under the auspices of the Committee, were devoted to venereal diseases, two meetings to industrial diseases, one to food, one to dispensaries, and one to hospitals.

The numerous applications of medicine to broad social problems like workmen's compensation, health insurance, health centers, industrial medicine, treatment of the sick in the homes, and pay clinics, claimed a great deal of the time and thought of the Committee. Public health teaching in medical schools, extension of the medical course to five years, opportunities for graduate medical teaching, advancement of medical science, the question of autopsies, better utilization of hospital and dispensary facilities, and nursing and dental education have likewise been frequently discussed and commented upon. The recent tendency in medical practice known as "group medicine" has been made a subject of special inquiry.

The Committee has ever striven to raise the standards of medical practice to make it serve best the interest of public health. With the same aim in view it combatted all legislation injurious to the health of the

community, like anti-vaccination, anti-experimentation on animals, the licensing of practitioners having no adequate preparation for the practice of medicine, the lowering of standards of civil service, and the like.

All the work done by the Committee could not but have its cumulative effect. Democracy does not function rapidly, changes are wrought imperceptibly. Moreover, that which is to endure does not grow fast. There are, however, a few definite achievements of the Committee which can readily be claimed. To mention only a few of them: (1) It was chiefly through the efforts of the Committee that the quarantine station at the Port of New York was turned over by the state to the Federal Government; (2) that dispensaries have abandoned the performing of tonsillectomies; (3) that the work of venereal disease clinics has been improved; (4) that an Association of Out-Patient Departments was formed and first attempts made to formulate standards for the conduct of clinics; (5) that the supervision of the poliomyelitis cases in the clinics during the post-epidemic period was continuous and payments by the New York After Care Committee made on the basis of this supervision; (6) that following the committee's dispensary survey, the Rockefeller Foundation appropriated a large fund of money for the improving of the dispensary service in the city and a Bureau of Dispensary Development was organized under the auspices of the United Hospital Fund; (7) that as a result of the survey of hospitals the Hospital Information Bureau was established in this city, also under the auspices of the United Hospital Fund, whose purpose it is to serve the community, the hospitals, and physicians with information concerning existing procedures and opportunities for further development. The aim of the Bureau is to collect, analyze, interpret, and make available facts and information bearing upon hospital needs and activities and the health interests of New York City; (8) that a health federation embracing all the health agencies of the city came into being and for several years played an important part in the budget making of the city departments dealing with health and hospitals. In 1913 that federation with the aid of the Committee published a very valuable study of an epidemic of typhoid fever in New York City; (9) that the Committee assisted in securing legislation abolishing the antiquated system of coroner and substituting the present

competent office of Medical Examiner; (10) that numerous changes of procedure and policy were made by the city departments; (11) with the aid of the Bureau of Municipal Research, the committee gave a six weeks' course on public health administration at the Academy which was attended by a large group of workers from many sections of the country.

### Child Health Current Study

One of the major studies on which the Committee is now engaged and which will probably take the larger part of the forthcoming year is that relating to child health. There is no one phase of social work which appeals to the public more than that of child welfare, and for no other phase of social work is it easier to raise funds than for that which concerns the child. As a result, a great deal has been started in this direction. There being no central directing agency, overlapping might easily have taken place. No one knows at the present time the extent of effort duplicated. No one knows which branches of child health have been adequately covered and which fields have been allowed to lie fallow. Furthermore, no one has attempted to evaluate the basic merits of the many activities comprised within the term "child health."

The study will likewise touch on the relation of private endeavor to municipal and state work. Should the private agencies limit their work to research, vigilance, and demonstrations, which, if proved to be of value, could be taken over by the municipality or state, or should they raise money to supplement activities which are recognized as municipal or state functions? And then, how far should the state or municipality go in providing care for the child—in other words, where should individual responsibility end and public responsibility begin? These are some of the questions with which the study of child health will deal.

The responses on the part of the public and the agencies concerned to all the requests and surveys of the Public Health Committee amply demonstrate the fact that the community is looking to the organized medical profession to supply leadership in the intricate social and public health problems lying on the border-line between civics and medicine.

Open air schools are maintained in the following towns in Indiana: Indianapolis, Fort Wayne, Evansville, South Bend, Goshen, and Marion.

# Sewage Disposal for North Side Chicago

A RECENT report by H. P. Eddy, G. W. Fuller, and T. Chalkley Hatton in regard to the disposal of the sewage of the North Side District of Chicago will be of wide general interest to all sanitarians. The area considered includes a group of towns lying along the shore of Lake Michigan from Glencoe to Evanston with a present population of about six hundred thousand persons, estimated to reach 1,450,000 in 1960. The average sewage flow in 1960 is estimated at 325 million gallons per day with a maximum of 500 million gallons per day. The sewage is to be discharged through the north shore channel and the north and south branches of the Chicago River into the Drainage Canal and the conditions governing plans for its treatment are stated by the Commission as follows:

The north shore channel lies within a residential community and the north branch flows through a portion of Chicago which is, or ultimately will be, closely built up. It is important therefore that the sewage should be purified to a degree which will prevent the waters of the channel and the north branch from becoming unsightly and giving off objectionable odors, and to this end the future deposition of sewage solids must be prevented and an adequate supply of dissolved oxygen in the water must be maintained.

The maximum average rate of flow of diluting water in the north shore channel and north branch is inadequate at the present time to afford the proper dilution of the sewage entering them and to prevent the deposition of sewage solids.

The effluent from the north side treatment works will be discharged into the upper portion of the system of drainage channels and will flow for a long distance through the highly developed portion of the Sanitary District. There will be considerable time within which the organic matter may exert its demand upon the supply of dissolved oxygen furnished by the diluting water.

Our survey leads us to believe that the demands of the main drainage channel require the completion at an early date of a plant of the size proposed for the north side area and capable of producing a high-grade effluent.

As a result of our investigation, we are of the opinion that inasmuch as the north side treatment works are to be built forthwith they should provide for a relatively high degree of purification accomplishing the removal of the suspended solids, the oxidation of the remaining organic matter and the production of a comparatively stable effluent.

The Sanitary District of Chicago owns a tract of 207 acres in the

Township of Niles suitable for the location of treatment works and it is planned to extend present intercepting sewers to bring the sewage to this point. These sewers will of necessity be so deep as to necessitate the pumping of sewage at the works.

Careful consideration has been given to all available methods and combinations of methods of sewage treatment, which may be subdivided into classes as follows:

Methods primarily for the removal of suspended solids such as fine screening, sedimentation and chemical precipitation;

Methods primarily for the oxidation of organic matter such as filtration through sand filters, contact beds, trickling filters and treatment by the activated sludge process; and

Methods primarily for the destruction of bacteria such as disinfection by the application of liquid chlorine, or by treatment with electricity.

From among these methods we have selected for study in detail those hereinafter mentioned which are capable of meeting the requirements, and which are practicable under local conditions.

## Projects Studied in Detail

Preliminary designs and estimates of cost of two typical treatment works were made by the engineering staff of the Sanitary District and furnished to us, namely: (1) Imhoff tank-trickling filter works; and (2) activated sludge treatment works.

In the case of the Imhoff tank-trickling filter works, the sewage is first passed through coarse racks or screens for the removal of trash. The sewage is then pumped to grit chambers through which it flows at relatively low velocity to permit of the deposition of heavy mineral matter. The sewage then passes to two story sedimentation tanks, the upper compartment being so proportioned as to permit the deposition of a large proportion of the suspended solids. After deposition, these solids pass through slots in the bottom of the upper compartment into the lower or sludge digestion compartment, in which the organic matter is permitted to remain for a period long enough to enable the organisms living in it to change the organic matter so as to render the sludge inoffensive. From the Imhoff tanks the settled sewage passes through fine screens and thence to the distribution system by means of which it is sprayed through nozzles over the surface of the trickling filters which are composed of broken stone several feet in depth. In passing downward through these filters the organic matter of the sewage is oxidized through the action of living organisms.

The effluent from the filters then passes through settling, or humus tanks in which suspended solids contained in the effluent are deposited.

The effluent from these tanks is free from objectionable odor, practi-

cally colorless, and contains but a very small quantity of suspended matter. The organic matter contained in this effluent is oxidized to such a degree that the effluent is stable and entirely suitable for discharge into the north shore channel.

The sludge from the humus tanks is pumped to digestion tanks. The sludge from these digestion tanks and from the Imhoff tanks will be drawn off at frequent intervals during the warmer portions of the year and applied to porous sludge drying beds upon which the sludge is allowed to remain until it has dried sufficiently to permit of economical removal and transportation to waste land where it can be used for filling.

In the case of the activated sludge works, the coarse screen, the pumping station, and the grit chambers are similar to those features of the Imhoff tank-trickling filter works. From the grit chambers, the sewage flows to and through fine screens for the removal of a portion of the suspended matter which might be deposited in the aeration tanks and interfere with their operation.

After passing through the fine screens, the sewage receives a portion of the sludge previously formed in the treatment of other sewage, and then flows very slowly through the aeration tanks. These tanks are provided at the bottom with porous plates through which a supply of air is forced continuously. The air leaving these plates passes upwards through the sewage and thoroughly agitates it, besides giving up to it a portion of the oxygen in the air. This treatment causes the separation of the finely divided organic impurities in the sewage into small particles which readily settle when afforded a suitable opportunity. After aeration for a period of several hours the sewage passes out of the aeration tanks into sedimentation tanks in which it is held in a practically quiescent condition for a sufficient period to permit the subsidence of the flow formed in the aeration tanks.

The effluent from the sedimentation tanks is clear, free from objectionable odor and practically colorless and free from suspended matter. The organic matter dissolved in the effluent is oxidized to such a degree that the effluent is stable and entirely suitable for discharge into the north shore channel. By this treatment a large proportion of the bacteria is removed.

The portion of the sludge withdrawn from the sedimentation tanks which is not required for the treatment of the incoming sewage is pumped into presses, or other equipment, provided for the removal of a large proportion of the water, the reduction being approximately from 98 per cent to about 80 per cent.

After dewatering in this manner, the sludge is conveyed to dryers which further reduce the moisture to about 10 per cent. The dried sludge is then ground, sifted and bagged ready for sale as fertilizer.

These two methods of treatment,

and a modification of the latter, have been studied in detail by this commission. The basic allowances upon which the estimates have been predicated are stated in the description of the appropriate projects, and are in accordance with the experience and judgment of this Commission.

### Filter Works

*Project 1. Imhoff Tank-Trickling Filter Works.*—This project provides for coarse screens for the removal of the large materials which might injure the pumps and other equipment.

It is necessary to lift the sewage about fifty-seven feet, for which an electrically operated pumping station is provided, with suitable standby equipment, or service, for use in case of interruption of the regular service.

Grit chambers are provided for the removal of heavy mineral matter that otherwise would be deposited in the sludge compartments of the Imhoff tanks, from which it could be removed only at substantial expense.

The Imhoff tanks are of such size as to retain the sewage for an average period of two and three quarter hours, for the deposition of suspended solids. The sludge compartment provides storage space of 2.3 cu. ft per capita.

The trickling filters are of broken stone 6.5 feet in depth and of a total area of 70 acres. These filters are designed to receive an average of 5,000,000 gallons of sewage per acre per 24 hours equivalent to 462,000 gallons per 24 hours per acre-foot of depth. With the rate of flow anticipated, this loading will be equivalent to the sewage from 11,430 persons per acre, or 1,750 persons per acre-foot of filter.

One of the objections to this type of filter has been that large numbers of little moth flies breed in, or near the surface of the beds. In some cases these flies have been the cause of considerable annoyance. Investigations made at Plainfield, N. J., in recent years, appear to have demonstrated that the breeding of these flies can be prevented by flooding the beds and allowing them to stand full for a number of hours. This project provides for this procedure and the area stated is based upon flooding one-seventh of the total area each day in rotation, thus providing for flooding the entire area once each seven days. This flooding is necessary only during the breeding season, which on the average may be taken roughly to be from April to October in this climate.

If the ten acres out of service be excluded from the computation, the loading of the remaining sixty acres will be at the rate of 13,330 persons per acre, or 2,050 persons per acre-foot. It is believed that the provision made for flooding the beds is sufficient to eliminate annoyance due to the moth flies.

The humus tanks provided are of the common single-story hopper bottom type, and of such size as to provide an average detention period above the hopper bottoms of one hour.

The project also provides two-story tanks for the digestion of the humus sludge. These tanks are similar in design to the Imhoff tanks, and their

use may be confined to the treatment of the humus sludge, or the humus sludge may be mixed with a portion of the incoming sewage, so that the humus sludge and raw sewage sludge may be digested together, as may prove the more advantageous.

The sludge drying beds are of the type in common use, and have been designed to provide 0.75 square feet of net filtering area per capita. The total net area of the drying beds is 14 acres.

Equipment has been provided for removing the sludge after drying and transporting it in barges to suitable sites now owned by the Sanitary District along the Main Drainage Channel west of the City of Chicago where the sludge may be deposited upon ground of comparatively little value.

As it is impossible to spray sewage into the air, as is done in distributing it over the surface of the filters, without the escape of some odor, liberal provision has been made for the isolation of these very large works. The estimated cost of this project includes a sum believed to be sufficient for the purchase of enough land to provide a strip one-half mile wide entirely around the works making the gross area approximately one thousand seven hundred acres.

This provision for isolation necessitates placing the works in the center of the tract at some distance west of the North Shore Channel. This involves some changes in the proposed intercepting sewers leading to the works. The net additional cost due to such changes is included in the estimate.

### Activated Sludge Works

*Project 2. Activated Sludge Works with Provisions for Dewatering and Drying Sludge to Convert it Into Commercial Fertilizer.*—This project provides for coarse screens, pumping station and grit chambers, as in the case of Project 1. The pumping station, however, is contiguous to and in fact, a part of the power station.

In this project the sewage is lifted about 33 feet, as compared with 57 feet in the case of Project 1.

The fine screens are of the mechanically operated type of which there are a number on the market. The estimates have been made large enough to provide for an adequate number of screens of suitable construction, together with necessary equipment for cleaning the screens and handling the moist screenings. For the purposes of this estimate, the aeration tanks are assumed to be 15 feet deep and to have a capacity 20 per cent in excess of that required to provide for a six hour detention period based upon the average rate of sewage flow; this excess capacity is provided for the return of sludge in the amount of 20 per cent of average rate of sewage flow. The quantity of air to be introduced into the sewage during the period of aeration is assumed to be at the rate of 1.25 cubic feet per gallon of sewage, although it is recognized that a smaller quantity may suffice for so dilute a sewage. The method of distribution and diffusion of air through the sewage by means of filtros plates is to be similar to that of the Calumet and the DesPlaines River Sewage

Treatment Works of the Sanitary District now nearing completion, and at Milwaukee, and to that which has been in successful use at Houston, Texas, for several years.

The sedimentation tanks are 15 feet deep, and have an area sufficient to provide 1 square foot of tank surface for each 1,600 gallons of sewage per 24 hours at the maximum rate of flow, no additional allowance being made for the volume of sludge which is removed from the bottom of the tank by means of suitable mechanical or other equipment.

The project provides for a sufficient number of filter presses for dewatering the sludge, based upon the results of investigations which have been carried out at Milwaukee during the last few years. It is expected that, if filter presses are used, it will be necessary first to treat the sludge with sulphuric acid, in order that it may be in the most favorable condition for pressing. While the estimates are based upon the use of filter presses, it is recognized that some other type of machine may ultimately prove more suitable for this work. It is believed, however, that the estimates are sufficient to cover the cost of such equipment. The sludge drying equipment includes rotary dryers and auxiliary machinery for conveying, grinding, sieving and bagging the sludge ready for the fertilizer market.

As the gases from the dryers may at times be somewhat offensive, provision has been made for removing dust from them and thoroughly washing them, in order to remove any offensive matter before their escape into the atmosphere. Experiments made at Milwaukee indicate that the gases may in this manner be rendered unobjectionable.

This project provides for a central steam power plant to produce power for driving the pumps for pumping the sewage and sludge, and for operating the air blowers and all other machinery required. The estimates are based upon the use of electric motor-driven centrifugal pumps, steam turbine driven blowers and steam turbine driven generators for furnishing current for electric motors for the miscellaneous needs about the works. The equipment is of ample capacity and includes a sufficient number of spare units.

It is estimated that about one thousand pounds of dried sludge can be reduced from each million gallons of sewage to be treated at the North Side Treatment Works, or about 85 tons per twenty-four hours in 1930.

The estimate of annual charges covers the cost of converting the sludge into condition for sale as fertilizer but does not allow for any credit from such sale.

### Sludge Lagoons

*Project 3—Activated Sludge Works with Sludge Lagoons.* This project is like Project 2 except that the equipment provided for dewatering and drying the sludge is omitted, and in its place provision is made for disposal of the sludge in lagoons.

Project 3 includes a force main from the treatment works to land now owned by the Sanitary District between the DesPlaines River and the

main drainage channel west of the City of Chicago. This force main is of cast iron pipe and about 18 miles in length. The sludge, as drawn from the sedimentation tanks, is pumped through this force main at a comparatively high velocity and discharged into lagoons of moderate size, from which the surplus clear water is drawn off into the main drainage channel. The remaining wet sludge gradually loses its moisture through evaporation and becomes compacted. By subdividing the area utilized for this purpose, it is practicable to fill the lagoons in rotation, applying successive portions of sludge until the lagoons become filled with solids.

The Sanitary District now owns a sufficient area of land, of comparatively little value, to provide for the disposal of sludge in this manner for many years.

Very careful consideration has been given to the question of whether objectionable odors will arise from such sludge lagoons. Repeated observation of somewhat similar lagoons at Houston, Texas, has in all cases indicated that there is an entire absence of offensive odors in the vicinity of such lagoons. We are confident that there is no danger of such odors in the vicinity of the proposed lagoons.

**Estimates of Cost**

The estimates of cost of construction and the annual charges of these projects are as follows:

Project	Cost of Construction	Total Annual Cost	Cost per Million Gallons Treated
1. Imhoff Tank—Trickling Filter Works...	\$16,266,000	\$1,766,000	\$27.84
2. Activated Sludge Works With Sludge Dewatering and Drying Equipment.....	14,503,000	2,210,000	34.60
3. Activated Sludge Works With Sludge Lagoons .....	13,203,000	1,751,000	27.42

The estimates of the cost of construction includes 15 per cent for engineering and contingencies, the cost of land already purchased, and the estimated cost of additional land required. The estimates do not include an allowance for interest during construction.

The estimates of annual costs include 5 per cent per annum for interest charges and also 1.783 per cent per annum, as a sinking fund sufficient to retire the investment at the end of 30 years. The estimates also include the cost of repairs and renewals, power, labor, and supplies.

**Merits of Projects**

Each project is capable of producing the required degree of purification. In each case there will be produced a substantial quantity of sludge containing fertilizing ingredients, principally nitrogenous organic matter.

In the case of Project 1, the quantity of fertilizing ingredients contained in the sludge will be so small that its profitable utilization as a commercial fertilizer is not promising, although there might be some local demand for it in the condition in which

it is removed from the drying beds.

The sludge from the activated sludge process contains more nitrogenous organic matter, and is in better physical condition for use as a commercial fertilizer, when properly prepared, than that from Imhoff tank-trickling filter works.

As activated sludge has not been placed upon the market as a commercial fertilizer, it is not possible at present to predict what will be the demand for it, or what price it may command.

The dewatering of activated sludge, which has been under investigation for several years, has proved to be a rather difficult process. While it has been demonstrated that this sludge can be dewatered, it is probable that improved methods will be discovered within a moderate length of time which will materially reduce the cost below that now indicated.

It is difficult to construct and operate such large Imhoff tank-trickling filter works so as at all times entirely to prevent the presence of the odor of sewage in its immediate vicinity. Such odors will be more noticeable about a very large works than about small ones. While it is believed that am-

gree of purification can be secured at substantially the same cost by another process, we conclude that Imhoff tank-trickling filter works offer no advantage for the treatment of the sewage of the north side area.

In view of the uncertainty of securing a market for the dried sludge, and of the price at which it could be sold, if there should be a market for it, and in view of the probability that improved methods of dewatering the sludge will be found, we conclude that it is not wise for the Sanitary District to undertake to convert the activated sludge into commercial fertilizer at the present time.

In view of the fact that works comprising Project 3 can produce an effluent equal in quality to either of the others; that such works can be built and operated for considerably less cost than those of Project 2; and that the sludge can be finally disposed of in an economical and unobjectionable manner, we recommend the installation of the activated sludge process with disposal of liquid sludge upon waste land, as herein described under Project 3, as the best system for the treatment of the sewage from the north side area.

The installation of Project 3 will place the Sanitary District in a position to take advantage of any improvements which may be made in the process of dewatering and drying sludge, so that if and when it shall be proved that the sludge can be sold for an amount equal to or greater than the cost of dewatering, drying and marketing the fertilizer, the necessary equipment for so doing may be provided. The Sanitary District is about to put in operation the activated sludge process at the Des Plaines River and Calumet Sewage Treatment Works where equipment has been provided for dewatering and drying the sludge, and it is quite probable that within a short period the Sanitary District will be able to determine how this work can be suitably done.

The area selected for the sludge lagoons is unusually favorable for such a purpose. The Sanitary District now owns a large area of land suitable for this purpose. The land is of comparatively low value, and is well isolated. It is properly protected from overflow by the easterly dike of the Des Plaines River, and is at such an elevation that the clear supernatant water from the sludge lagoons can be drawn by gravity, or pumped with only a slight lift, to the main drainage channel.

This locality is suitable for a de-

ple provision is made in Project 1 for the isolation of the works, it is recognized that there may be a noticeable odor immediately adjacent to them, and that such odor will be observed by persons using the highways in the immediate vicinity of the works.

Although the development of the little moth fly has proved objectionable in the immediate vicinity of some trickling filters, it is believed that the development of such flies to any substantial extent can be prevented by the means provided.

The disposal of activated sludge by lagooning in a suitable locality as proposed in Project 3 does not appear to involve any danger of objectionable odors, and is much less expensive than its disposal by any other means, unless substantial return can be obtained for it as a fertilizer.

**Recommendations Made**

Because of the possibility of objectionable conditions in the immediate vicinity of Imhoff tank-trickling filter works, and because an equal de-

watering and drying plant and it may well be that such a plant could serve several sewage treatment works should these ultimately be provided for the treatment of the sewage of the Sanitary District.

In closing, the opinion is reiterated that the activated sludge process recommended for the north side area is readily capable of producing an effluent entirely suitable for discharge into the north shore channel and will conform to the requirements of the Act of 1921 of the legislature of the State of Illinois requiring the treatment of sewage by

the Sanitary District of Chicago.

This report seems particularly noteworthy for two things, (1) the abandonment of the hope of securing financial return from the manufacture of commercial fertilizer from activated sludge until better methods of dewatering such sludge are devised; and (2) the attention given to the problem of controlling local nuisances. It is primarily the freedom of the activated sludge process from the danger of creating such nuisances which has led to its adoption, a consideration that recommends the process.

the experimental work possible deserve thanks for what has already been accomplished and the cooperation of all who are able to give help in the solution of the worthwhile task that they have undertaken.

### Health Commissioner Wins Seat in Senate

Royal S. Copeland, the first New York doctor to win a seat in the Senate, owes his success principally to his activities as health commissioner of New York. It is safe to say that almost up to the very moment he was nominated last summer the thought of serving the Empire state in the upper house of Congress never had entered his mind. It was the great surprise of his career states the *Times*, when the news came to him that he had been selected as the senatorial candidate. The next surprise probably was the return which showed that he had defeated Senator Calder, veteran Republican politician, by a landslide vote of more than 200,000. Dr. Copeland will be one of two physicians in the Senate. The other is Senator Ball of Delaware. Senator France of Maryland also is a physician, but his name will not be on the roll-call.

Dr. Copeland is a native of Michigan, and once upon a time, long before he decided to go to New York, was mayor of the university city of Ann Arbor. He is a graduate of the University of Michigan, and in preparing himself for a medical career took postgraduate courses in France, Germany, Belgium, and Switzerland. Twenty-two years ago he went to New York to accept the directorship of Flower Hospital, and he was still the head of that institution when offered the post of health commissioner by Mayor Hylan. In his campaign the doctor surprised his friends by the vigor of the fight he put up. He proved that he knew a lot about other things than medicine, among them the tariff, the high cost of living and subjects which might be properly classed under the head of "humanities."

To raise the health standard of the children in his rural district to that of city children is the aim of Superintendent Arthur B. Lord of Topsfield, Mass. During the past year a school nurse has been employed and every child in the town given a physical examination by the school physician and nurse. Formal physical exercises were also introduced into the school.

## Sub-Committee on Plumbing

THE attempt to simplify plumbing regulation is included in the general work of standardizing building regulations that was started last year by Secretary Hoover as a part of the effort of the Department of Commerce to decrease the cost of living. The first tentative report of the sub-committee on plumbing of the Department of Commerce Building Code Committee has been given a limited circulation among technical and industrial organizations, architects, health officers, plumbers, and plumbing inspectors, and others who have shown special interest in the subject.

This sub-committee, under the chairmanship of Prof. George C. Whipple of Harvard University, is also at work on a code of standard plumbing rules that will be issued as a supplement to their final report. The tentative report recently issued, after dealing with the extent of plumbing equipment subject to control, the reasons for public control, and of the legal principles involved, describes the lack of uniformity in present plumbing code requirements and their methods of administration. Standardization of plumbing materials is a much desired advance but under the varied requirements of different states and municipalities it is obviously impossible. If the committee succeeds in the formulation a model code that the states will be willing to adopt the greatest obstacle in the way of simplification of fixtures and the consequent lowering of cost will have been removed.

The experimental investigations of the committee are being carried on at the Bureau of Standards and were at the time the first report was issued limited to house drainage systems applicable to one-story, one-family, and to two-story, two-family dwellings. In

accordance with the request of the committee, the exceedingly interesting and valuable findings in regard to design of fixtures, size of pipes, rate and duration of flow, and related facts is given but this brief mention.

Among the most interesting conclusions that the committee have reached are that a soil stack three inches in diameter is sufficient to give adequate service in an ordinary two-story dwelling; that a house trap or running trap is under most conditions not only unnecessary but undesirable; that a certain amount of venting is usually necessary to make traps safe against back pressure, self-siphonage and siphonage by aspiration; but that an individual vent for each trap is not necessary and that group venting is satisfactory under certain conditions specified in the report.

This proposed attack on the useless if not harmful running trap in the house drain is an excellent step in the right direction. Many authorities would like to see the entire abolition of the costly procedure of back-venting traps, but from its experimental work the committee still feels that group-venting must be continued in most installations.

The final report of this committee promises to be an epoch-making event in the economics of health and housing of the people. The cost of plumbing installations has been, and still is a large item in the total cost of house construction. The simplification of plumbing with lowered cost will extend its use thereby safeguarding the health of the people; better housing will follow and it will be a little easier for the working man to own his own home.

Secretary Hoover, the members of the committee, and the officials of the Bureau of Standards that have made

# Health Building Through Nutrition Work

## The New York Tuberculosis Association Builds for the Future

BY M. ALICE ASSERSEN, M.D., SECRETARY, CHILDREN'S SERVICE, NEW YORK TUBERCULOSIS ASSOCIATION, NEW YORK CITY

**I**N RECENT years we have been startled by the fact that from twenty to twenty-five per cent of the children of the present generation are suffering from malnutrition—a serious condition which, on account of its accompanying lowered resistance, exposes them to the risk of acute and chronic disease, especially tuberculosis. With the knowledge that a large majority of children already harbor tuberculous infection before they reach adolescence, we are faced by the problem of overcoming this serious defect—malnutrition—which is so frequently a forerunner, if not actually a symptom, of tuberculosis.

### Malnutrition Defined

Malnutrition is a condition of undernourishment—a symptom, frequently, of disease as well as a condition arising from insufficient or improper diet. It may be a symptom of chronic disease, or the result of acute illness. Often it is caused by physical defects or faulty methods of living. It is due generally to a combination of several factors which makes it a complex problem requiring for its correction thorough medical and social work.

There are certain characteristics which we find in a large majority of instances, and these are more likely to be present in children whose weight is ten or fifteen per cent or more below the standard weight. These are: pallor of face and mucous membranes; dull eyes, with dark circles under them; muscles so flabby and poor in tone that they are unable to support the body in an erect position, leaving the shoulders stooped or rounded. The chest is flat and narrow, the abdomen prominent and the back curved in at the waist line.

We find two distinct types among these malnourished children: one, dull and apathetic, listless, tired; the other, overactive, nervous and irritable, capricious, and difficult to manage. Children showing these characteristics are found among the rich as well as among the poor.

### Causes of Malnutrition

Some cases are due to poor inheritance and prematurity, which may exert a baneful influence throughout the life of the individual. Acute disease, especially if severe and prolonged, such as measles, whooping cough, pneumonia, etc., naturally may result

in malnutrition. Chronic conditions such as heart disease, syphilis, renal disorders, frequent gastro-enteric disturbances are often accompanied by this condition; but tuberculosis, of all chronic diseases, is reckoned to be one of the most frequent causes of malnutrition.

Some of the physical defects causing malnutrition are carious teeth, bad posture, obstructed nasal breathing (especially when due to the presence of adenoids), and diseased tonsils.

Dr. A. K. Krause of Johns Hopkins University, has recently emphasized the great importance of a clean, healthy mouth in the prevention of tuberculosis.

If the lymphatic glands which drain the mouth are weakened by a constant fight to eliminate bacteria and pus from bad teeth and diseased tonsils, the resistance to the specific tubercle bacillus is diminished, and it may become impossible for the gland to exert its usual protective power by destroying, or enclosing these organisms within the protecting barriers of connective tissue, so as to make them harmless for the person infected. The important thing, therefore, from the viewpoint of tuberculosis, as well as from that of the correction and prevention of malnutrition, is to avoid and to remedy conditions such as unhealthy mouths, which interfere with the normal protective function of the lymphatic glands.

### Improper Diet

Among the other causes of malnutrition, besides disease and physical defects, are insufficient food, which may be due to poverty, or to the habit of eating too little; or to badly prepared food because of ignorance in cooking, or to indulgence in rich, indigestible food such as pastry, candies and rich cakes, or to improper food not suitable to the needs of a growing child, like tea and coffee, instead of milk. Children need nourishment, not only for the maintenance of life and the repair of tissue waste, and to furnish heat, strength and energy, but—what is more important still for the growing child—food that will build new tissue and assure his

Nutrition class at health exhibit of the New York Tuberculosis Association under physician's instruction on proper foods and health habits.

These lads are all fit subjects for the corrective methods of nutritional class management. Combined with a history of exposure, they are potentially tuberculous.

proper and full development. He must have animal proteins for this purpose, such as are contained in meat, eggs, and milk. He must also have a proper amount of lime, phosphorus, iron, and vitamins.

Faulty food habits such as eating between meals, eating irregularly and hurriedly, gulping food and washing it down with liquids, all have a direct bearing in contributing toward malnutrition in children.

Insufficient rest and sleep, or too strenuous exercise, or entertainment of too exciting a nature, are frequent causes of malnutrition in children. An early bed hour, and rest for an hour at least during the day, are important habits to establish in a child's daily routine.

Sleeping with closed windows at night, or remaining too much indoors during the day, may also bring about a malnourished state.

Constipation, by reacting upon the general health, may be responsible for the existing malnutrition.

The important underlying social factors causing malnutrition may be poverty, resulting in bad housing, overcrowding, insufficient and poor quality of food; and ignorance, resulting in unclean and unsanitary conditions in the home, unintelligent buying of food, spoiling it in cooking; and lack of parental control which either neglects or over-indulges a child and allows him to form habits which are detrimental to good health.

The prevention of malnutrition

should begin first in the proper care of the expectant mother before the child is born, guarding her against disease and abnormal conditions, incident to her pregnancy, advising her as to proper food both for herself and for the nourishment of the baby. After the birth of the child, the prevention of malnutrition lies in the maintenance of a sound body, the provision of clean, wholesome surroundings, sufficient and proper food, and the formation of habits that are conducive to health, as well as the early correction of physical defects.

In the treatment of malnutrition, excellent results have been obtained by the combination of the individual and class method, which utilizes the spirit of the social and competitive instincts and thus stimulates not only children but parents as well.

Nutrition classes can be organized wherever groups of children may be assembled. A physician should be available for the class, or arrangements should be made whereby members may be referred to neighboring clinics for medical examination, supervision and correction of defects; secondly, there should be a special social or nutrition worker provided.

The size of the class should be limited to twenty or twenty-five children, as experience has taught that better results can be obtained by working with small groups, where necessary individual attention need not be sacrificed.

The success of the class will depend

upon the selection of competent workers, who must be experienced in practical social service work, know something of food buying and food values, and have a love for children as well as an intelligent knowledge of handling them individually, or in orderly groups.

The first step in organizing a nutrition class is the selection of the children for whom this work is needed. In order to do this, the nurse or nutrition worker must ascertain the weight, height, age, and social history of the children.

Children under six years of age should be weighed without clothing, and the older ones with only indoor clothing and without shoes. Those who are 10 per cent or more below the standard weight are usually the ones first considered for membership. The standard weight tables prepared by Dr. T. D. Wood for the Child Health Organization will be found very useful.

The children selected in this way should then be invited to meet once a week. At the first session they should all be submitted to a careful medical examination, not only for the purpose of discovering the possible causes of the undernourished condition, but also to ascertain whether it may be due to disease, or to physical defects, and to determine and classify the grade of malnutrition; for although the standard weight tables prepared are an invaluable aid in selecting cases of malnutrition they are nevertheless a single index only. It is necessary in judging malnutrition to consider other elements such as the general "make up" of the child, the proportion of fat and muscle, whether his bones are small and comparatively light, or large and heavy. The racial and family characteristics must also be considered so as to determine whether he belongs to those of large or of small physique.

A record of the physical examination, habits of the child, and, so far as is possible, the social condition of the family should be entered upon the record sheets prepared for this purpose.

It will be found helpful to give to each child, at the close of the first session, a little blank book to be used as a "diary" throughout the week—the hour of rising and going to bed each day, the time of each meal and the food taken, whether or not eating between meals was indulged in, the amount of time spent out-of-doors, etc., to be noted. Many of the older children find it interesting to estimate the number of calories in the food taken each day.

**WEIGHT TABLE for BOYS**  
Weights and measures should be taken without shoes and in only the usual indoor clothes.

to allow one-half of the class to compete against the other half. The individual weight chart alone is often stimulating, as interest is aroused in trying to reach the goal, the red line drawn across the chart indicating the normal weight.

These methods are not only stimulating to the children but to the parents as well, who are invited and urged to be present at each class session; for without the interest and cooperation of those in charge of the home, and of the child, little can be accomplished.

After the first thorough examination, the children should be re-examined at the discretion of the physician in charge, but always before graduation.

The weekly weighing should be conducted in a formal manner so that the child may be impressed with its importance. Graduation from the class should be based upon the amount of gain made—for instance, a child who has attained his normal weight and who has held or exceeded it for two consecutive weeks may be graduated, and should be given honors, provided he has observed the rules of health and has had dental and other physical defects corrected. It should not be

forgotten that the value of the nutrition class depends not only upon the actual improvement made by the individual child, but also upon the amount of health education which has been acquired by both child and parent.

After graduation the child should be made to feel that he still belongs to the class, and should be invited to return about once a month to be weighed and to participate in the exercises.

Vacancies made in the class by graduation should be filled at once from the waiting list of eligible members.

**Class Equipment**

Comparatively little equipment is needed to conduct a nutrition class. The essential things are: scales, individual weight and record charts, a table of standard weights for reference, stars—red, blue, gold, and silver—record books for daily happenings, chairs or benches for the class, a desk or table, and a screen and examination table.

It will always be found helpful to have the use of a gas stove or range in order to conduct special cooking demonstrations for mothers, sisters or older girls in the class.

**Gains and Variations**

Among practical difficulties arising in the conduct of nutrition classes at various periods of the year is that of the normal seasonal variations in weights of either children or adults. The recent report of the New York Nutrition Council gives valuable statistical indications, to guide the worker in charge in understanding the individual weight progress. It has been found, by a study of 977 individual records of children, under the care of the New York Association for Improving the Condition of the Poor,

Parents should be urged to accompany their children to the class sessions, as it is important for them to understand the condition of the child, so that they may be willing and better able to cooperate with the physician and nutrition worker.

After the preliminary work of selecting and examining the children is over, the next step is a visit to their homes by the nutrition worker to learn something of the conditions under which they are living, and to advise the parents as to personal and home hygiene, with special reference to the formation of good habits concerning rest, exercise, fresh air and proper food, and to emphasize the advice given by the physician as well as to assist, if necessary, in securing the correction of physical defects.

A weekly session of the class should be held, the children being weighed each week and the weight entered upon the individual charts. The height need be taken only every three or four months.

The charts should be hung, during the class sessions, in the order of weight gains, so as to bring attention to the good results.

Individual attention should then be given to each child, especially to those who may have lost weight, by obtaining from both child and parent an accurate history of the week's events. When this has been accomplished, an interesting and instructive talk on some health topic should be given, either by the physician or by nutrition worker.

There are many methods in use for arousing the interest of the children in their health progress. One way is to award stars of different colors for gains in weight, cleanliness of teeth, daily rest, drinking of milk and for the correction of defects. Another plan is to establish an Honor Roll, or

Boy, formerly malnourished, but who at the time of graduation from nutrition class had gained nearly thirteen pounds in nineteen weeks.

that the average monthly gains were distributed as follows during the year:

DISTRIBUTION OF MONTHLY GAINS OF GROWING CHILDREN THROUGH THE YEAR.

	Boys	Girls
January	9.9%	8.3%
February	7.6	6.7
March	6.4	5.6
April	4.7	5.3
May	3.7	—
June	0.9	0.5
July	3.9	5.4
August	13.2	12.3
September	15.0	16.6
October	14.8	15.6
November	12.3	15.3
December	7.6	8.4
	100.0%	100.0%

With the gradual elimination of preventable diseases in modern life nutrition work during childhood and adolescence, interpreted in its broadest sense, as a means of awakening the consciousness of the child to his own physical condition and training him in health habits, should prove to be one of the most valuable health movements. The young adult who faces active life with a healthy body will at least be assured an equal opportunity and capacity both for the proper enjoyment of life and for contributing his full share to the progress of the world.

### Milk-Borne Diphtheria

Very unusual epidemiological facts were revealed by an outbreak of diphtheria that occurred in Austin, Texas, in the spring of 1922. A few cases of an extraordinarily virulent form were reported in January and February. Soon after the onset of the disease both tonsils were covered with a thin milky-looking membrane that shaded gradually into tissue that appeared normal without any sharp line of demarkation. The mucous membranes were not of the usual vivid red. The membrane, which involved an unusually large area, appeared simultaneously in several parts of the throat and soon developed a dirty black appearance.

Toward the latter part of March the outbreak began to assume serious proportions. Seven cases appeared at about the same time among a group of students at the University of Texas that took their meals at the same boarding house. A month previous to this time a cook at the boarding house had been ill with diphtheria and her baby had died from the same disease. The cook could not be found as she had been discharged at the time of her sickness; the interval between her departure and the first appearance of the disease was too long to fix responsibility on her; the other cases were scattered ir-

regularly throughout the city; and the origin of the epidemic was still unknown.

The university authorities asked aid of the state health department and as the outbreak had been too explosive to be due to ordinary carriers they suggested an investigation of the dairy that was supplying milk to the students' boarding house. The milking at dairy B was done by Mr. S., his wife, and their son. Visual examination of these three as well as four younger children in the family revealed apparently normal throats, and none of them had a recent history of illness or sore throat. Cultures from the entire family revealed *B. diphtheriae* in the throat of Mr. S. The grandchild of the proprietor who lived on the premises about a hundred yards from the dairy was found to be seriously ill with a dark, extensive, necrotic membrane that was typical of this epidemic. She had not been near the dairy nor handled any utensils since she became ill.

The herd consisted of fifty-one graded Jersey cows. A large number of them had cuts and abrasions of the teats and udder due to the barbed wire fences so common in that state. One cow had three teats covered with thick black scabs which when removed left a ragged ulcerating surface. Cultures from these sores were positive. At this stage the investigators believed that Mr. S. was a chronic carrier; that he had infected the cow; and that the grandchild had been infected through the milk. The usual control measures were inaugurated; the infected cow and her milker were quarantined, and the sale of the milk was stopped.

Mr. S. insisted that the infected cow had the sore when he came to work at the dairy early in January and that before that time the herd had been milked by Mr. M., his wife, and child who were now milking for dairy Z. At the time of this disclosure two new cases of diphtheria were reported among the customers of dairy Z. Nose and throat cultures were taken of the milkers at dairy Z and all proved negative except the culture of M.'s nose. Further examination revealed a perforating ulcer of the septum. This ulcer which had existed for four years had been diagnosed syphilitic, and several treatments administered. Repeated cultures from this source gave extremely virulent *B. diphtheriae*.

The final conclusions of Graham and Golaz, of the Texas State Depart-

ment of Health, who report this unusual epidemic in the *Journal of the A.M.A.*, October 14, 1922, are that Mr. M. infected the cow at dairy B while milking there previous to January 1. The cow was dry at that time and was not milked till February 1, shortly after which date diphtheria appeared among the dairy customers; the cow infected Mr. S. and the grandchild of the proprietor and the majority of the cases in the city were infected from the milk. The investigators state that it is puzzling to explain the explosion of new cases late in March.

In this atypical epidemic of 71 cases, 80 per cent were among adults and 52 of the cases were traced to infected milk. This experience shows the need of careful inspection of dairy animals in all milk-borne epidemics and the value of nose cultures.

### Drug Adulteration Shows Large Decrease

Drug adulteration is on the wane according to experiments of the Connecticut Agricultural Station at New Haven which reports that out of nearly four hundred specimens of United States Pharmacopoeia drugs examined only sixty-two were found adulterated, below standard or otherwise illegal. Most frequently, derelictions were found in the case of bay rum, essence of peppermint and similar products, which have no great significance in therapy. Even solution of calcium hydroxid, which so often has left the druggist's shelf as moderately pure water, having parted company with its content of lime during a prolonged sojourn there, is found to be up to standard with reasonable frequency.

Only a few years ago there were extremely few "honest" diabetic foods. Today the number of reputable products with truthful claims is largely increased. Yet Bailey's report shows the sale of a "starchless breakfast food" containing more than 64 per cent of starch, not to mention the additional sugar content. There are "glutenized" cereal products containing 50 per cent of starch and soluble sugars, yet recommended for diabetic patients. Gluten products containing more than 65 per cent of available carbohydrates, and therefore no more suitable than ordinary wheat bread for the diabetic, are advertised still; but they have lost their former prominence in the face of an educated medical profession and a cautioned purchasing public.

# Public and Private Health Agency Relationships

BY ROYAL S. COPELAND, M.D., COMMISSIONER OF HEALTH, NEW YORK CITY.

THE duty of protecting the public health is the particular business of governmental or official health agencies. When the exercise of this function is defective or neglected, the members of the community, individually or collectively, have a legal right and a moral obligation to ascertain the causes of such defect or neglect, and to attempt to correct conditions.

In the last analysis, the responsibility for the character of the health protection rendered a community rests not only with the officials who are charged with such duties, but with the citizens of that community as well. Just how far public service should extend is open to debate. There can be no doubt that it is the duty of official agencies not only to exercise police authority for the protection of the public welfare in general, but to establish and conduct medical and educational services which the poor require and which are not otherwise provided.

When a catastrophe or serious epidemic occurs, distinctions and differences as to the rights and prerogatives of official as against voluntary agencies naturally disappear for the time being. An imperative work has to be done. If the official agencies have been far sighted and have prepared themselves to cope with such emergencies, they are logically in exclusive command of the situation. If not, any voluntary agency having the means and ability to render aid is justified, in stepping in to fill the breach. Aside from such grave emergencies, however, private individuals or organized groups, it seems to me, should not assume the exercise of functions which are properly the business of official health bodies. Since official agencies are responsible for the failure or success of their health protective measures, they must have undivided authority and full jurisdiction in the performance of such work.

It would be both unfair and unwise to hold official health organizations responsible for the proper discharge of their duties and obligations to the community, unless with such responsibility there went unhampered and undivided authority to direct and conduct such work. When authority is divided, the blame for failure cannot be properly placed. Moreover, a public agency which is

expected to perform a responsible and important piece of work calling for the exercise of administrative functions, is handicapped rather than aided by unnecessary competition of private agencies in the conduct of its activities.

In the interest of good citizenship, it is desirable and necessary that groups of citizens in every community should organize to serve as vigilance committees, exercising influence to compel official bodies that may be lax or incompetent, to render effective service. This is the paramount service private agencies have to perform.

Any agency that assumes to conduct community health service which should properly be performed by an official health body, is guilty—though it may not be conscious of it—of an unsozial act, unless incompetence, indifference or poverty of a community government make it imperative for citizens to take up arms for their own protection. If officials will not or cannot perform functions which are properly theirs, it is not the business of private groups to supplant them, but to bend their efforts to the instruction or reform of such officials, or to the procurement of moral and financial support to establish or strengthen the health organization of such official bodies. Private groups which seek to serve as substitutes for official agencies, do little except to produce demoralization and to delay the establishment of good and efficient government.

## Should Be Supplementary

Private organizations interested in public health activities should be the closest allies and warmest supporters of official health bodies. Unfortunately, this natural relationship is frequently conspicuous by its absence. Volunteer organizations, having their origin in a desire to create and support necessary official health machinery and activities, sometimes have a way of perpetuating themselves long after the conditions that justified their birth and existence have ceased. Following the recent war this was illustrated in a number of communities.

Public service should not be regarded as a medium for earning individual glory. There is no occasion to be exercised over credit denied a given individual or unjustly ascribed to another. Virtue should be its own

reward; but, it is, of course, quite human and reasonable for those who, like Hotspur, are begrimed and sweated with the toil of battle, to resent the criticism of non-combatants, or the decoration of those who have not borne the brunt of the day's labor. Moreover, in a discussion of inter-relationships of public and private agencies one must take stock of the lesser things which conspire to mar harmonious relations between public and private health agencies if these minor complaints are not to continue to cause friction. A frank diagnosis of the causes of ill will must precede efforts at correction.

Public health officials, whose duty it is to furnish information with reference to their activities to individuals or groups in the community, are, in their turn, disturbed when such information is secured by workers in private health agencies and utilized without acknowledgement or credit. Private health agencies, especially those desiring campaign material to obtain financial contributions from generous citizens, cannot be excused if they publish accounts of health activities in which either directly or by implication they may seem to claim credit for results which are due to the activity of the public health officials. The official agency needs to receive credit, not for the gratification of the vanity of those in charge, but to justify their course of health supervision so that they may be assured of further support for activities having to do with the public welfare. It is absurd for any private health agency, in making bids for contributions, to claim credit for a falling death or sickness rate, when even a judge with the wisdom of Solomon could not determine all the causes for such a decreasing rate. It is exactly as if a historian writing of the activities of foreign and remote events which have come to his knowledge through documents were to write as if he were the chief actor in the activities or events which he describes.

It is safe to say that no voluntary health agency is properly organized if it is not striving for its own effacement. Nor is this the harsh and hostile dictum it seems. It is obvious, that if an agency has set itself the objective of awakening in the community a public sentiment on the need for efficient and adequate machinery for

health protection, such agency should not divert its efforts toward obtaining financial support of an independent organization for the purpose of conducting the health work which they claim a desire to promote. The voluntary agency should not replace or supplant the official health body. In direct proportion as voluntary measures are successful in stimulating health officials to the performance of their duty, or in creating public understanding and sympathy and in helping to secure adequate funds for the conduct of public health work, they will have lessened the need and excuse for the continued existence of parallel bodies and should prepare to retire from the field. This, of course, does not apply to groups that act merely as vigilance committees to maintain standards of municipal or governmental efficiency, free from political motive or self-interest.

It is alleged that a few voluntary agencies that have grown greatly in social and financial power have not stopped short even of attempting to impose their judgment and decisions as to objectives, methods of procedure, and the conduct of health services upon official health agencies. This has resulted quite naturally in bitterness and in conflicts.

#### A Parallel Case

An analogy may serve to show the fallacy of the present methods of such private health agencies. Let us assume that in a community whose police department renders inefficient or insufficient service, a private association has undertaken to remedy the situation by organizing and maintaining a private police service for the community as a whole. Obviously, this would be a most demoralizing, undemocratic, and subversive form of private service. Good citizenship requires that the best elements should unite for the creating of a public sentiment that would compel the correction of the defects or evils that may characterize an inefficient governmental police department; or such public sentiment should aim to secure adequate financial support to make the existing police department efficient. A private police service would inevitably cause duplication of work. The resulting confusion and conflict, would cause a delay in the correction of the evils or deficiencies in the public service, that would aggravate and intrench such evils or defects. Moreover, lacking the authority to assume the police power, it would weaken the authority and dignity of the governmental agency.

The community would not suffer from the termination of some of the private agencies that concentrate their efforts upon the special activities designed to stimulate a flow of public contributions to their own organizations. The contrary would be the case, for sound civic policy dictates the preservation and enhancement of official governmental agencies. Private health organizations could with great benefit to all devote their enthusiasm and energy to the support of the official bodies. Financial support by the public of philanthropic institutions is necessary and commendable; but the financial support of private health agencies is of very questionable value, since it inevitably tends to convert such agencies into groups that are zealous to compete in the exercise of functions which sound civic policy and the general welfare demand should be performed by the official health organization.

The volunteer or private health agencies are of service primarily in small communities, or in areas where official health activities are very primitive and undeveloped, or where the official agency is very deficient in the quality of its service. In the larger communities, especially in the chief cities of the country, in most instances volunteer agencies have no right to exist unless they mean to serve as vigilance committees or research bodies.

#### Recapitulation

(1) There is the need of private health agencies to serve as vigilance committees. The phrase "vigilance committee" is perhaps inappropriate in that it implies an attitude of hostility on the part of citizen groups, as the need is for groups of public-spirited citizens, well organized, who are united to support and encourage general progress in public health work, who are content to serve as friends and allies of the official health bodies, and who will throw the weight of their social influence in favor of securing more adequate support for such official health agencies.

(2) Such voluntary associations may give valuable aid in conducting experimental or research health activities in order to determine the value of some new method of procedure which the local or state government may later be asked to adopt.

(3) They may legitimately supplement the work of official health agencies by financing and maintaining social service activities for which funds or personnel are not available.

In conclusion, I would say that there is sufficient opportunity for service by private health agencies in the fields which I have just described. If they will accept this limitation, there is glory enough to go around and, what is more important, the public service and welfare will be greatly benefited.

#### Increased Mortality Affects Advanced Ages Chiefly

The higher mortality rates which have prevailed during the first six months of this year have affected chiefly the ages beyond 45 years, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company. At ages under 25 years, the deathrate declined sharply. The decline in the deathrate for children under 15 years resulted from the lower diphtheria, scarlet fever and whooping cough rates; among adolescents the lower tuberculosis mortality was the chief factor back of the lower rates. The deathrate was approximately five per cent higher this year in the age group 25 to 34 years. This increase resulted, from the most part, from the higher rates for influenza-pneumonia and organic heart disease. In the age period 35 to 44 years, the rate for all causes of death this year was only 4.3 per cent in excess of the figure for 1921, and the increase seems to have been caused by higher deathrates for influenza-pneumonia and cancer.

The more significant increases in the 1922 mortality record have occurred, however, at the more advanced ages. For the age division 45 to 64 years, the deathrate for the first six months of 1922 was 12.3 per cent and, at the age group 65 years and over, 13.3 per cent in excess of the figures prevailing during the same period of 1921. The chief factors responsible for higher mortality at these advanced age divisions were organic diseases of the heart with an increase of 21.6 per cent between 45 and 64 years and of 20.1 per cent at ages 65 and over. There was a considerable increase in mortality also for chronic nephritis, cerebral hemorrhage and apoplexy, cancer and influenza-pneumonia.

According to Dr. Wood in the *Journal of Education*, 15,000,000 of the 24,000,000 school children in the United States suffer from remedial health defects, malnutrition being the most common with visual defects second.

## The Problem of Obtaining a Good Milk Supply\*

PURE food propa<sup>g</sup>anda is so far effective in the United States that, other things being equal, the products "made in daylight factories," and packages "not touched with hands" find the readier sale, and at what may often be considered a disproportionate advance in costs in the open market. In the case of milk, however, a relatively greater cost in preparing and handling for the market is both scientifically and humanely necessary for the promotion and maintenance of the highest degree of physical health, for the universal use of milk as a health measure presupposes that the supply shall be safe.

Milk products must not only be pure, but they must uniformly present standard food values and must be delivered daily on every doorstep. Every handler must accord it the precise care as to cleanliness and temperature regulation necessary to prevent the deterioration of a highly perishable product. Safe practice in regard to such a commodity of necessity imposes sanitary methods. Standardization, which safeguards the consumers in placing a minimum limit on the butter fat content of milk, also suggests to the farmer the necessity for a careful weeding out of ineligibles from his herds, replacing them with animals whose products in quantity and quality will enable him to meet the economic problem involved in providing milk in such quantities and at such prices as will make it available to all the people all the time.

Who is responsible for the evolution of the dairy industry? More especially, who is responsible for its ethics? For ethics it is that imposes such complex regulation and enforces its continuous observance.

Health officials, bearing in mind their onus of sampling and inspection, and of policing in times of milk-borne epidemics, claim full credit for the reforms that have taken place in the milk business in the last decade. The dairy interests, however, point with pride to their trade organizations, national and international, formed for express purposes of research and for the development of laboratory tests and sanitary methods as a basis for the rating of cooperating members. Nor are their organizations lacking in the machinery to keep in line recalcitrant members who fail to conform to these self-imposed standards.

citric members who fail to conform to these self-imposed standards.

Twenty years ago the dairy farmer peddled his own wares. If here and there a dairyman by habit more careful than the rest provided a relatively safe product, he was the exception rather than the rule. There were no clean dairies in the present meaning of the term. No tests of herds were made, no certification as to fat content, no feeding tests as to vitamin principles. Sanitary standards as to handling were unheard of. Sales of milk were made as widely as the farmer's output would permit and no cooperative effort was made to meet the demands of an exacting market. If perchance the course of typhoid or diphtheria coincided with the route of a careless milkman, it passed unnoted, and the "hand of God" was seen in the affliction.

In view of the conditions, it is perhaps just as well that reform came both from within and without. The health authorities had occasion enough for their activities in cleaning up the milk situation. Opposition on the part of milk producers to the increasingly exacting demands of health departments has gradually fallen off until at the present time it would be a bold, bad dairyman indeed who would propose to return to the older methods, and

such a course would spell his ruin. All over the country a marked tendency is shown among dairy farmers to cooperate with distributors in each progressive movement.

Naturally, the process of achieving this unity of practice has not been carried on without some opposition, and unreason has from time to time characterized both the health department and the industry. Even now in some sections the protagonists of tuberculosis-free herds advocate drastic methods that would needlessly reduce the milk supply, are economically unsound, and are probably not called for by the situation. B. tuberculosis is not the only pathogen which constitutes a menace in milk. The reasonable safe-guarding of herds and pasteurization are the solution. Nor is a low bacterial count the only criterion of safe milk. Economic hazards likewise attach to some minimum fat requirements that are advocated. The fat content of milk varies with the breed of cattle, with the method of feeding, and with the season. Inflexible requirements and an inordinately high fat content do not allow for this variability and would involve standardized herds and wholesale replacement of present dairy cattle. In the light of newer investigation on nutritional lines it may well be that the

\*The pictures presented with this article are from the plant of the Gridley Dairy Company, Milwaukee, Wis.

Glass-lined pasteurizing vats, each holding five hundred gallons. Vats like these were formerly used exclusively for beer. Now they are very properly devoted to the proper handling of milk, the great American beverage.

Cooling room, where the temperature of the pasteurized milk is immediately lowered to around 38 degrees. The mosaic tile ceiling and walls, and concrete floors throughout the building are steam-cleaned and made sterile.

calcium and vitamin values rather than fats will determine gradations in milk, and that biological experiment will replace present methods of test tube trial.

What the ultimate values are will be scientifically determined. The dairy interests themselves are indefatigable in research both as to food values and as to the basic economics involved. The World's Dairy Congress set for 1923 is a scientific assembly, convened primarily to determine precisely what the standards should be, and how it can be made economically possible to make right practice universal in the dairy industry.

Milk production and distribution are of no inconsiderable importance. The expense for production and distribution has wide economic bearings. The most extensive study bearing upon the cost of handling proportionated to the ultimate cost of milk on the market was made by Mr. Hoover's special milk committee of which Dr. Clyde L. King, of Wharton's School of Finance, Philadelphia, was chairman in a detailed study of seven distributors in the cities of Milwaukee, Madison, Racine, Eau Claire, and Kenosha. The combined output of these dairies amounted to twelve million dollars, their products being distributed to more than eighty-nine thousand retail and wholesale customers through nearly four hundred wagon and auto route, practically all their sales being made by drivers

either to family or store trade. On a total of 173,000,000 pounds of fluid milk and cream, the handling costs averaged about a cent and one-half per quart, the dealers' profits 3.32 per cent of the total sales.

The "know your school" slogan could well be supplemented by the admonition "visit your milk plant." Investigation may not reveal reme-

diable conditions, but it may be very enlightening as to how an entire factory is operated under laboratory conditions. An up-to-date milk plant of one hundred twenty thousand bottles daily capacity involves a factory floor space of 197,000 square feet, not allowing for country receiving stations. Three chemical laboratories are required, 710 workers employed, and the plant requires 1,400 h.p. boiler capacity and a 100-ton refrigerating plant. The nature of the work requires showers, rest rooms, all day and all night lunch rooms for employees as well as special installations of many kinds. The floors of the plant inspected are all of cement, fully drained; the walls and the ceilings are all of mosaic tile, beautiful to look at and easy to clean. Hot and cold water under high pressure, and live steam available everywhere are a part of the sanitary provision. Specially adapted apparatus and exacting routine procedure take care of the rest. A repair shop constantly employing thirty men, painters, tin-smiths, coppersmiths, etc., runs 365 days in the year, some of the men on duty all the time, Sundays and holidays as well as the usual work days. An electrical and engineering department employs sixteen men, including the chief. A wood-working shop, blacksmith and harness shops, and a veterinarian department are maintained.

The milk is collected in eight gallon cans. It is received at the plant

Bottling room, where twenty thousand bottles per hour are automatically filled and capped. Along the route by which the bottles are carried on a moving belt each bottle is flushed with thirty gallons of hot water under thirty pounds pressure.

by the sampler and his assistants, subjected to the most severe tests, the weight of each can carefully noted, and then the milk dumped into a huge vat from which it is pumped to the top floor. The empty cans, including those owned by the farmers making delivery to the plant, are then treated to a rapid process of washing and sterilizing, every can being flushed by not less than 250 gallons of scalding water forced into its innermost recesses at a pressure of twenty-five pounds. The bottles also receive the same treatment with the exception that each bottle receives thirty gallons of water in the process of sterilization.

From the glass pasteurizing vats on the top floor, the milk is distributed throughout the plant by the gravity system. Pasteurization is carried out by the usual standard of 145 degrees F. for about thirty minutes. The milk is then carried through the cooling room where the temperature is immediately reduced to 38-40 degrees. It is then automatically bottled and capped, and held at constantly low temperature pending delivery.

The law in Wisconsin provides that whole milk—nothing added and nothing taken away—shall be delivered to the trade. The legal requirement that it shall carry a minimum of 3 per cent butter fat is exceeded by the actual tests, which run from 3.5 to 3.8 per cent. Cream under the law may be standardized and the practice is to deliver three grades of cream, 18, 23, and 32 per cent respectively. The fact that milk producers are paid on a basis of the fat content serves to interest the farmers in scientific feeding. Samples are taken every day and tests made at ten day intervals and records are kept of the product. The farmer is notified of any undue amount of sediment. The paper carrying the evidence of dirt accompanies the notice to the farmer to clean up. In the past some few dairies made a selling point of handling clarified milk, a practice which the National Association itself remedied by requiring "clean, not cleaned" milk.

Where dairies prepare and handle such by-products as butter, cheese, and ice cream, the same meticulous care is exercised in these special departments. In the plant inspected a log has been kept of every churning. The record of acidity, salt and moisture percentage makes it possible to check back to any single churning of a total output of three and one-half million pounds of butter a year in order to discover and correct any faulty condition. The several laboratories

One of the laboratories where samples of milk are taken to be analyzed as to fat content, sediment, acidity, and bacterial count.

keep continuous record of the daily analyses for fat content, sediment, and acidity. Samples are taken at random from the cold room. If the Board of Health gets samples, the daily routine of the factory analysis affords parallel tests for comparison.

In the Wisconsin study quoted comparison was made on the basis of "points," one point being the equivalent of a quart of any kind of milk, or one-half pint of cream. Two points comprised the daily average delivery to a customer. The lowest average of customers per route was 161, the highest 242. The average cost of delivery per customer was \$14.87 per year. The expense of the dairy plant,

exclusive of the cost of milk, was one-tenth of the net sales. The three dealers who maintained the lowest costs were the same ones who set the highest daily averages in points delivered per route. The widest margin of profit also accrued to the dealers who emphasized scientific method. A low cost in handling carries its health correlation in the increased consumption of milk. An understanding of the economic background of better milk production will lessen arbitrary insistence upon non-essential requirements and will serve to hasten the day when good milk will be plentiful and cheap enough for anybody to use. It is an economic problem of magnitude.

## The Nurse as an Educator

SOME of the many things which a nurse should know and do in her position as private nurse to make herself a valuable factor in venereal disease control are recounted by Ann Doyle in *The American Journal of Nursing*, September, 1922.

(1) She should be acquainted with the subject of venereal disease, at least sufficiently well to enable her to discuss the condition of patients with physicians without incurring their displeasure. (2) She should know the federal, state, and city provisions for control, in order that she may lend moral support to the physicians in getting cases of venereal diseases reported. (3) She should be

familiar with the various agencies and societies interested in social hygiene and the prevention of diseases, in the community in which she lives, in order that she may gain assistance in getting objectionable conditions corrected. (4) She should be careful to consult physicians of the highest professional reputation. (5) If she is morally certain that the patient for whom she is caring is not being properly supervised and public health is endangered thereby, she should seek redress through medical fraternity whenever possible. (6) She should not discuss venereal disease cases in any way which might do damage.

# Health Twins at Work

THE animated cartoon with its flavor of humor and frivolity hardly seems a suitable means for conveying a forceful and dignified message but the reception by health workers of "The Public Health Twins at Work" produced by the American Social Hygiene Association proves that the limitations of the possibilities and versatility of the motion picture as an educational instrument have not yet been reached nor defined.

The scene opens on a courtroom where the judge representing Public Opinion presides. Two sprightly clever little men, the public health twins, are introduced respectively as Science and Administration with the explanation that "the control of disease depends upon science and administration." The judge orders the three culprits, tuberculosis, infantile diarrhea, and diphtheria to stand before him and when they have taken their places all else of the scene except the three prisoners fades out and the caricature of tuberculosis slowly dissolves into a vertical bar. In quick succession the other two figures are likewise transformed into vertical bars, the resulting picture being a bar graph of the mortality rates of the three diseases in 1900, each bar being carefully titled and of proper height in relation to the other.

The scene changes to the prison chamber. The public health twins drag the prisoners and hypnotize them into vertical bars. These bars are hammered down by Science and Administration to the condition shown in Figure 10. More serious than any of these diseases, says the title, are gonorrhoea and syphilis, commonly called the venereal diseases. The scene is again the prison chamber. Venereal disease is brought in and hypnotized into a bar but so tall is it that it extends beyond the top of the screen and the twins look skyward in amazement. One twin seizes a hammer labelled "Medical Inspection of Prostitutes" and shins up the bar. The other twin remains below looking up but presently dodges to escape being hit by the hammer which has been broken off at the neck of its handle. Another hammer labelled "Publicity" is tried, but though the sparks fly it seems to make little impression on the bar.

The twins are discouraged but finally evolve a plan consisting of many measures which, intelligently combined and supplied, hold out hope of ultimate success. Then a new tool box containing an assortment of hammers representing enlightenment of public opinion, repression of prostitution, control and treatment of those who are infected, supervised recreation, better economic and social conditions, and character training is secured. The twins seize the hammers and rush up to the top of the bar where they begin their rhythmic pounding with obvious success. After a title "And in a few years—why not?" the scene is once more moved down to the bottom of the bar where the twins are still at work pounding the bar closer and closer to extinction.

Titles for the pictures are as follows: 1. The judge, "Public Opinion." 2. One of the twins, Science and Administration. 3. Tuberculosis and Infantile Diarrhea awaiting sentence. 4. Diphtheria grows excited in the court room. 5. The judge pronounces sentence. 6. All but the three prisoners "fade out." 7. The prisoners "dissolve" into bars. 8. In the punishment chamber where tuberculosis is "hypnotized" into a bar. 9. Hammering down the tuberculosis rate. 10. The result of twenty years work. 11. "Venereal diseases" being hypnotized into a bar. 12. Hammering the V. D. bar. 13. The hammer "Medical Inspection of Prostitutes" has been broken. 14. The V. D. bar hammered down.

# Health Officers' Opportunity for Research\*

## Rural Districts Offer as Good Field For Epidemiological Study as Cities

BY DR. BURDGE P. MACLEAN, HEALTH OFFICER, HUNTINGTON, N. Y.

THE rural health officer, like the country doctor, too often permits himself to be persuaded that his limited territory necessitates limited opportunity and limited activity. Too often he is led to believe by the people of his district that investigation of so-called nuisance is paramount, and that poking and smelling about dumpheaps, manure piles, and overflowing cesspools should be his end and aim in life. Too often he is dissuaded from honest investigation by that attitude of resentment which is often assumed by uninformed and misinformed individuals, which attitude disappears and is converted into one of cooperation, in the great majority of instances, when the purpose of his investigation is made clear.

By promptness, by vigor of action, and by utilization of the epidemiological and laboratory assistance at his command, the rural health officer has an opportunity for medical, clinical, and epidemiological research denied the central office man and the health man of large communities.

His limited territory is turned to his advantage. A bloodhound is of more service in Green River, than he is on Broadway, New York. He keeps the scent and trees his man. In the big city the tracks are lost. Smallness of his district does not imply smallness of the bump of curiosity on the head of the health officer nor lack of opportunity. There is much to be learned and the opportunity of finding the key to many problems may come to the country doctor. Beaumont was a country doctor when he did his great work on the stomach; ovarian surgery got its start when a country doctor, MacDowell, had the courage of his convictions. These facts, therefore, furnish a hope that through preparedness and alertness the knock of opportunity may be heard at the door of the lesser lights and result in a real service to humanity and the realization of legitimate ambitions.

This matter of preparedness needs definition. Emphasis upon the following factors would no doubt lead to more accurate and abundant epi-

*"By promptness, by vigor of action, and by utilization of the epidemiological and laboratory assistance at his command, the rural health officer has an opportunity of medical, clinical, and epidemiological research denied the central office man and of large communities.*

There is much to be learned and the opportunity of finding the key to many problems may come to the country doctor."*

demiological and scientific data: (1) The help of the physicians in a community in promptly reporting to the health officer not only the communicable disease, but the usual and obscure disease. (2) The employment of a uniform method in obtaining data, such as that furnished by the state department in its regular investigation cards, or in special instances, on a card devised by the health officer himself. (3) Prompt cooperation in the outbreak with the district sanitary supervisors and the state laboratory men. (4) Close liaison with the local boards of education, school principals, school teachers, school nurses, school doctors, and truant officers. (5) The maximum amount of information concerning his territory in possession of the health officer—such as sewer and water maps, names and addresses of customers of leading milk dealers, data concerning waste from factories, gasworks, etc.; a sanitary map designating potential disease breeders, such as neglected dump-heaps and filthy families.

With this general information

available and the way paved for immediate cooperation between himself, local physicians, and the state department investigators, the health officer has at hand at least the preliminaries requisite for the investigation of anything, usual or unusual, that may occur.

During the past year six outbreaks of different kinds have occurred in and about my vicinity which furnish valuable suggestions for research even though they have led to no definite conclusions.

At the hamlet of Coram on Long Island, during the month of February, the host and hostess at a church social allowed their thirteen-year-old son to leave his bed, where he had been confined by the early stages of influenza, that he might join in the festivities. Forty people promptly developed influenza. Seventy-five per cent of these were among the fifty that had attended the social. This outbreak clearly illustrates the importance of early stage infectiousness and the training of the public as to the need of isolation of the so-called common cold.

In August, at Millers Place, L. I., an outbreak of diarrhea followed the sale of ice cream at a ball game. A delay in the plating of fecal specimens terminated in investigation that was started.

Six cases of food poisoning in the members of one family resulted in two deaths at Port Washington. No results could be obtained because of no notification till after the fatalities had occurred and because of the lack of a skilled pathologist.

At another time delay in reporting caused a lost opportunity for research in respect to five severe cases of infectious jaundice.

An outbreak occurred at Sayville following a turkey supper given by a lodge of Odd Fellows on May 24. One hundred and forty-five persons attended this supper, nearly all had diarrhea promptly following, and thirty sufficiently ill to call a doctor. Crampy abdominal pain, diarrhea, light brown to greenish foul-smelling stools, high temperature, and prostration were the predominating symptoms in those obliged to seek treat-

\*Presented at Annual Conference of State Sanitary Officers and Public Health Nurses at Saratoga Springs, N. Y., June, 1922.

ment. There were no fatalities and all had recovered by the end of a week.

The outbreak, unfortunately, was not called to the attention of the health officer or sanitary supervisor until three days after the feast, and therefore no food remained except the same brand of canned peas which had been used, the contents of which cans proved to be perfectly good. The supper had been prepared by four reliable women, none of whom had had any form of intestinal disease. Examination of the stools of three of the victims disclosed a para-typhoid bacillus, not the human *B. paratyphoid*, but the variety found in animals.

The building in which the supper was held is known to harbor rats and mice and it is possible that the food infection may have come from this source. Investigation of this outbreak is still in progress, the organism isolated being tested against known strains of *B. paratyphoid*, and active campaign of rat and mouse catching going on to determine if similar organisms can be found in them. Had this unusual trouble been brought more promptly to the attention of the health officer or sanitary supervisor more might have been learned from the food which was eaten. The presence of the unusual organism in the stools of those sick, however, suggests the possibility that outbreaks which have been considered due to ptomaines may be the result of animal infection.

### Contagion on Milk Route

In the township of Huntington during the thirty days preceding May 3, 1922, there had been reported four cases of scarlet fever, all widely separated and bearing no relation to each other. This was not startling in a township of 15,000 people. On May 3, 1922 between 12 and 12:30 p. m. there were reported to me fourteen cases of scarlet fever. Fourteen cases in half an hour was startling. An immediate canvass of these cases showed on the complete investigation cards of the state department the following facts:

The cases were widely separate; had no personal contact; the youngest was 18 months and the oldest 67 years; they had all developed sore throat on the 1st and 2nd of May and a rash on the 3rd and—they all took milk from the same dealer.

This information was obtained in about two hours' time and by 3 p. m. the trail had led straight to a 19-year-old son of the milk dealer, who,

with his father, was most concerned in the milking. He had a sore throat which a culture later showed to be due to the *Streptococcus hemolyticus*; he had a cough as the result of inhaling smoke at a brush fire; but—he had no rash when first seen and had not observed a rash previously. Nor did he subsequently desquamate. Nevertheless, it is most probable that he had scarlet fever. A streptococcal throat, a cough, and an open milk pail spelled trouble. He was at once isolated, the sale of the milk stopped for twenty-four hours until all apparatus could be sterilized to destroy residual infection and an examination of the cows made by a competent veterinarian. This examination disclosed a particularly healthy lot of cows, only one cow showing an insignificant scratch on one teat, which cow, to be absolutely safe, was excluded from the milking.

The board of education agreed without question to the health officer's advice in regard to the inspected open schools and gave permission for the employment of two extra school physicians. These physicians, with the school nurse, the district public health nurse and the health officer, made daily morning inspections of all school children, and the afternoons were devoted to the investigations by the school and district nurses and the truant officer of all absentees.

This follow-up work of absentees yielded more results than the school inspections: for while no cases of scarlet fever were discovered in the schools, three cases were found in children who had been kept home from school by their parents in fear of their "catching" scarlet fever.

Between the dates of May 3 and 10, fifty-two cases of scarlet fever were reported and all were on the route of this one milk dealer. The date of onset of the last case reported was May 10,—just seven days from the time the infected milker was excluded from the milk.

The milk dealer on whose route the trouble originated owned 15 cows, produced about 160 quarts of milk a day, which was delivered to 91 families consisting of 390 persons. In cooperation with Dr. Overton, Dr. Noble, and Miss Williams of the state department, this route was thoroughly gone over, not only for scarlet fever but for other diseases. Twenty-nine cases of sore throat were discovered, these throats presenting an identical appearance with those accompanied by a rash, but with milder constitutional symptoms. Adults and children who had recently recovered from

measles were especially susceptible to both the sore throat and scarlet fever. The combined sore throats, with and without eruption, numbered 81. Forty-seven throat cultures were taken and of these, 33 showed *Streptococcus hemolyticus*. A map of the milk route was made, customers being indicated by black dots, scarlet cases by red circles, and sore throats by green circles. No matter where the black dots led the red and green circles followed. In other words, a map of the milk route was a map of the scarlet fever and sore throat. Neither scarlet fever nor sore throat developed in families where the milk was boiled. The scarlet cases varied from extremely mild to severe. In some instances the rash lasted only a few hours. Vomiting was infrequent: the temperature range was from 101 to 105; the "strawberry tongue" was seen late or not at all; complications did not occur, and there were no deaths. The one constant symptom was sore throat. Desquamation occurred in 61.2 per cent of the scarlet cases and the amount of desquamation was in direct proportion to the amount of rash. None of the sore throat cases peeled. None of the scarlets or sore throats had had scarlet fever previously.

The outstanding points of interest in this epidemic are—its absolute limitation to the milk route of one dealer, the streptococcal hemolytic throat in the milker whose exclusion from the milk was followed in the expected time by a disappearance of the outbreak; the isolation of a similar organism from the throats of a large number of cases both with and without a rash; the absence of contact cases; the lack of complications and the zero mortality. The sore throat cases merged into the milder scarlet fever cases and seemed to be the same disease minus rash.

### Scarlet Fever Research

Dr. Noble is working on the remaining step in this investigation to determine if the hemolytic *Streptococcus* found in the throat of the milker is of the same strain as that found in the throats of the other individuals who got sick from the milk. When all data concerning this epidemic are collected and complete, the information thus obtained may throw light on the debated question as to the identity of septic sore throat and scarlet fever.

Is scarlet fever a *Streptococcus* infection, or is the streptococcal invasion the result of lowered resistance due to an unknown virus? The ab-

sence of definite scarlatinal symptoms in the milker in this outbreak, the simultaneous occurrence of scarlet fever and septic sore throat in the milk consumers, the presence of what appears to be the same organism in the throats of both, and the prompt checking of the outbreak by isolation of the infected milker seem to give added importance to the streptococcus as the causative agent in scarlet fever.

While the descriptions of these six occurrences or outbreaks led to no definite scientific conclusions, they do lead unmistakably to the fact that opportunity for research is seldom lacking in a community no matter how small it may be.

An earnest effort to convince the physicians of a town or village of the importance of promptly working with the health officer, not only in the con-

tagious disease, but in the obscure and unusual disease, prompt cooperation of the health officer with the state department and utilization of the laboratory and nurse facilities which the department affords—these things may, when least expected, lead to beneficent results, and make of the health officer a sanitarian in every sense of the word, and not merely a machine for routine daily work.

An anti-mosquito conference under the auspices of the State Board of Health of Florida was held at Daytona December 6 and 7. This conference is the culmination of a season's intensive work by Chief Sanitary Engineer George W. Simons, Jr., under whose direction the details of the meeting were arranged. At this conference the general problem of mosquito eradication was discussed.

attached chart be given fair consideration.

Unfortunately, the discussion of this subject has always been involved too much in sentiment and not sufficiently with fact. Men make up their minds that because the thesis that the mortality trend is unfavorable in later life is pessimistic, it is to be condemned; but if we are to have a clear and well balanced interpretation of the facts, we must exclude all matters of sentiment, being neither optimistic nor pessimistic, but cold-blooded students of this question, and give fair consideration to all the facts bearing upon it.

Dr. Dublin has lately produced some figures from the Metropolitan experience which do not support this thesis of any special influence from the epidemic in affecting mortality trend at middle life and later. This, of course, applies to life insurance policyholders—a selected class. Nevertheless, he has advised caution in interpreting these figures. And all who discuss this matter should fairly present the facts relating to the whole experience of the decade and not risk their conclusions wholly upon a comparison of 1920 with 1910. That an abrupt and remarkable change took place in the trend of mortality from these diseases in 1919 is evident not only in America but in British mortality. In 1920 there was a moderate rebound; and even in life insurance experience as reported by the Metropolitan Life Insurance Company, there has been a decided increase in the mortality from these diseases in 1922 as compared to 1921, i.e., an increase in the death rate at age 45 to 60 of 21 per cent in 1922 as compared to 1921, largely due to an increased rate for the organic maladies.

This question of extending the life span beyond age of fifty and of improving the physical condition and working capacity in these later decades of life is still the greatest health problem that confronts civilized man.

## Mortality Controversy

THAT the mortality from degenerative diseases of the inter-census years must be analyzed to gain information from these diseases past middle age as well as the rate in census years is the contention of Dr. Eugene Lyman Fisk, medical director of the Life Extension Institute, who takes exception to the statement of I. S. Falk that "the available statistics indicate that the apparent increase in the mortality from these 'degenerative diseases' to whatever cause it may have been due in the past, has in the last decade given place to a decline."

Mr. Falk's article, "Mortality Past Middle Age," which appeared in the August NATION'S HEALTH was in turn called forth by M. T. MacCarty's discussion of the same topic in the April issue in which Dr. MacCarty argued that the hygienic emphasis which has effected a saving of life in the lower age groups has had no influence on the increasing death rates at middle life.

Dr. Fisk's letter and chart are published herewith:

While Mr. Falk is pretty severe in his criticism of other essayists who have been concerned about this apparent upward trend in the mortality from chronic organic diseases, he has himself omitted to consider some possible fundamental fallacies in his interpretation of the census statistics of 1920 as compared to 1910. Wholly ignoring the tremendous fact of the influenza epidemic of 1918, his concluding paragraph would give the impression that there has been a gradual improvement in the mortality from these diseases and at the later ages of

life. This subject is too broad and complicated to be disposed of in this off-hand manner and by the mere presentation of surface statistics. It is incumbent upon us to analyze the inter-census years and not to accept too hastily the implication of one census year as compared to another. As a matter of fact if that portion of the decade between 1910 and 1917, inclusive, had been compared with the decade 1900 to 1910 (or even with the year 1910) there is no question at all but that a heavy increase in the mortality from the degenerative diseases would have been shown; and presumably a concomitant increase in the death rate at middle life and later. A consistent and well proportioned presentation of this subject requires that the factors plainly evident in the

# Housing to Secure Individual and Civic Health

## Disease and Delinquency Follow Overcrowding and Insanitation

By BERNARD J. NEWMAN, MANAGING DIRECTOR, PHILADELPHIA HOUSING ASSOCIATION, PHILADELPHIA, PA.

THE house is a powerful influence for good or evil in the lives of its occupants. If it is structurally safe and in a sanitary condition, it protects its tenants from certain safety hazards, or from exposure to conditions that would tend to lower their vitality or bring them in contact with organisms largely responsible for causing disease. If it is overcrowded or dirty, if it lacks adequate light and ventilation, is damp and attracts those insects that are carriers of disease germs, it is a menace to public health. The effect of housing defects may be of only gradual growth but it is none-the-less certain to appear. The only safeguard against its occurrence is the elimination of the cause. That is, "safety first" in housing requires the prevention of insanitation, structural deterioration, overcrowded occupancy or like evils that make a dwelling less fit for human habitation.

Insanitary houses work their greatest harm on children. The younger the child, the less able he is to overcome adverse influences. Child mortality is highest where home conditions are bad. Children's diseases are more prevalent in areas where homes are built closely together and there is greater frequency of contact between the sick and the well. It is more difficult to prevent disease among children when they are in close contact with filthy conditions, or where insects like the fly, the louse, the bed-bug or the mosquito are attracted to, or breed near, the home or person. Child growth is stunted in mind and body where the home is poorly ventilated, inadequately lighted, or overcrowded.

Morality is harder to inculcate in the child who sees immoral conduct commonly practiced by the occupants of overcrowded rooms. The highest percentage of delinquents coming into the courts, either as juvenile offenders or adult criminals, are from a bad housing environment. In like manner the adult finds the poorly ventilated and dirty home a predisposing cause for pneumonia, tuberculosis, and other respiratory diseases. With scarcely an exception, other things being equal, morbidity and

mortality rates are highest for people living in insanitary homes. There is a vast mass of data available to show that health, mortality, and civic righteousness are most common in the good house in a good neighborhood.

It is commonly believed that bad housing is found only in big cities. This is a mistake. It is found also in the small cities, mining towns, and country villages. As a matter of fact, an individual dwelling standing far away from other houses may be so poorly designed and equipped, in such had repair and kept in such a filthy condition that its tenants may be subject to almost as grave hazards to health and well-being as a family in the city slums.

### Housing Fundamentals

In determining the safety of a house for occupancy, certain fundamental requirements should be taken as a basis of measurement. The building should be so constructed as to secure for each room adequate light and ventilation. Light is required for clear vision, for its germicidal value, as well as for its psychological effects. It aids in cleanliness in that it reveals dirt. To get adequate light not only should each room have ample window area, that is one-tenth of the floor area, but the windows should be so placed that the light which enters may be distributed throughout the room.

Adequate window area does not necessarily imply adequate light. The glass should be transparent and window panes kept clean. Dirty window glass may shut out 30 per cent to 50 per cent of the light. Closed shutters, so often found in rural houses, to protect the carpet from fading, nullify the purpose of the window. Windows opening on narrow yards or courts have their value reduced if the open space is too narrow to permit a 45 degree angle of light at the base of the window. In old buildings, if additional window area to off-set a low angle of light is not feasible, the reflecting walls of the adjacent building should be whitewashed or painted white. In like manner, if halls or rooms lack adequate light, the walls and ceiling should be

painted a light color not only to increase the light of the rooms but also as an aid to cleanliness.

Windows serve in most American houses as a means of ventilation as well as of light. Ventilation, or air in circulation, provides under ordinary conditions, air fit for breathing. It dispels dampness, removes odors, supplies an adequate amount of fresh air. Windows should open top and bottom and, where the need requires in winter, should be provided with inexpensive ventilators in the form of deflecting boards or cloth screens admitting air but preventing chilling drafts. At night, in summer and winter, windows in sleeping rooms should be open. Night air, contrary to general belief, is beneficial and not harmful.

Right conditions of ventilation call for air neither too dry nor too moist. Air without adequate humidity dries the mucous surfaces of the body, exposes persons to respiratory diseases, and increases the cost of adequate heating. In like manner air that is too moist has a detrimental effect and interferes with the normal functioning of the body. The danger of too dry air on the one hand or too moist on the other is very real in homes where families are poor. In winter, especially, where all the members of the family congregate in the kitchen and burn lamps and cook their meals with doors closed and cracks stuffed with paper and rags, the hazard is very real.

Houses with windows opening only upon narrow side yards, alleys, or courts are more difficult to ventilate than houses with windows opening upon unobstructed areas. Likewise, rooms with windows on only one side are difficult to ventilate. It is good practice to have windows on two sides of the room or, if this is not feasible, windows so placed in relation to the doors that through circulation of air may be obtained. Abnormal temperature in summer may be avoided on top floors if attics or air chambers are between the ceilings of such floors and the roof. Without exception, houses without studding or without an air space between the plaster and the brick or stone wall are more dif-

fault to heat, and if normal temperature is not maintained by furnace or stove their walls will become damp. The same condition is found in cellars not ventilated and in cellars with dirt floors of certain soil. To remedy such a condition daily ventilation of the cellar and concreting of the floor are necessary. Walls may become damp if the pointing of bricks or stones is not maintained.

### Sanitary Equipment of House

Of importance almost equal to adequate light and ventilation is the sanitary equipment of the house to provide an ample supply of pure water and the safe removal of liquid wastes. Where the town provides water from a common filtered source, the householder is mainly concerned to see that it is piped within the dwelling. This secures a supply from a spigot in the kitchen, with the sink beneath and a properly trapped drain leading therefrom. A spigot in the yard involves unnecessary and at times hazardous exposure to the weather. It is desirable to have an additional supply to a bathroom that a bathtub may be installed. If the town does not provide pure water, the next best source is the artesian well. Often a shallow well or a spring is available and used. In such a case no privy, stable, or similar source of pollution should be near the well, and its sides should be enclosed in non-permeable masonry, leaving only the bottom open to permit the filtering of water. The top of the well should be covered with concrete or well matched flooring, so laid that the drain will be away from the well, and a drip-trough supplied to take away the surplus from pumping. If the supply is from a spring, regardless of its proximity to the house, the spring should be protected in the same manner as the well. Should the supply be from a cistern, extraordinary precautions are needed to protect the water. Attaching deflectors to the down spout will insure the cleansing of the roof of dust, bird dung, and trash before the rain water is sent to the cistern. Covering the cistern, periodically cleaning the tank, and an occasional dose of a harmless disinfectant will make the safety of the water certain. Water for washing purposes may be stored in a hogshead or container for days at a time, but it is well to use fresh drawn water for drinking purposes and to keep pails for this water covered when not in use. These pails should be thoroughly cleansed each day with soap and water.

The delivery of water to a house necessitates a system for taking the waste water away. Dwellings should be sewer connected, and equipped with a sink, a bathtub and an indoor flush toilet, each properly trapped to prevent the pollution of the air of the house with drainage odors, and all should have plumbing installation of the "open" type. Where there are no sewers, disposal to a septic tank is advised and in the absence of this, the dry closet is recommended. If a privy vault must be used great care is necessary to keep the vault free from leaks, fly-screened, and periodically disinfected with lime. The process of disinfection, prior to the final disposal of all feces from persons ill with a communicable disease, would reduce the hazard of the privy vault. Yard sites for water closets are undesirable: the water frequently freezes, and their use is discouraged by bad weather, this latter causing an interference with the normal functioning of the bowels. The long hopper closet is the most preferable for outdoor use. This should be kept clean, in good repair and no solids such as cloths, or brushes, forced into it, for clogging of the drain will result.

Other household wastes besides sewage are garbage, ashes, rubbish, tins, old paper and like materials. Where the town collects such wastes the householders' only care is to see that garbage, ashes, or tins are placed in receptacles and other wastes are securely bundled. When the householder must dispose of garbage that decays, attracts vermin, and gives off unpleasant odors, burning or burial are good methods. The puncturing and flattening of tins that they may not collect water will prevent breeding of mosquitoes. Never store trash in cellars or back yards. Householders should discourage the creation of so-called "dumps" in depressions or on vacant lots except for the disposal of ashes and clean earth from excavations, but where dumps are used for all sorts of waste they should be frequently burned over.

### Keeping Floors Clean

The proper disposal of waste matter is a great aid to cleanliness but there are other aids equally important. Simple matters as floor sweeping are often neglected or poorly done. Floors with loose dirt soon become begrimed. They are hard to clean and suggest uncleanness of person and a careless manner of living. The common practice of sweeping dirt only out of sight under

large objects or down cellar stairs is a menace as well as being slovenly.

This practice causes dustiness and where communicable diseases are present gives bacteria dirt particles to which to become attached, and they, in every gust of wind or rustle of air, rise to the breathing level of the householders. Such accumulated dust becomes a menace to the children who creep or play on the floor. In a house where sweeping and dusting are not properly practiced every article of furniture, loose wall paper, and all rough surfaces become dust collectors.

But cleanliness requires more than allaying dust. Greasy walls where paper has neither been renewed nor cleansed are, especially in dark rooms, a cause for the retention of bacteria of certain respiratory diseases and become a medium for their spread. Even repapering over old paper may contribute a health hazard in an unclean and poorly lighted room. Painting exposed surfaces is a most wholesome preventive of uncleanness as it lends itself so readily to scrubbing. It is better than wall paper for all walls but especially those where the light is poor or the rooms are used for the care or handling of foods. The best germicide introduced into any home is soap and water with a good muscle and scrubbing brush to make them effective. The use of soap and water safeguards against vermin spreaders of filth and carriers of disease organisms, the cockroach, bed-bug, fly, and other insects attracted by dirt. Screening of windows, proper storage of foods, and covering of waste receptacles, rat-proofing of spaces between floor beams and the exclusion of animals from the house, all contribute effectively to the sanitation of the home.

Cleanliness within a building has a more direct bearing on the health of the occupants than cleanliness without but it is equally effective, out and in, to have conditions suggest orderliness. Thus the graded lot, the grass plot, trees and shrubbery, open fences instead of high board barriers contribute their share toward making the householders more healthy minded and more alert to wholesome suggestions for his physical, mental and moral betterment.

Another factor to be considered is the safety of the structure for occupancy. Most buildings when erected are safe. The hazard comes from their use after disrepair sets in. Some disrepair is only a trivial safety hazard, such as torn wall paper. Other disrepair, such as loos-

ened plaster, may, depending on its location, be a menace. Leaky roofs usually are disagreeable, but when they contribute to damp rooms and walls they affect health. Poorly pointed walls likewise contribute to dampness; they eventually cause buckling and bulging of the walls, the support of the wall load is displaced and collapse is imminent. A broken step or weakened stair often appears as a minor disrepair but may become a major hazard where children are about or where inattention may cause one to trip and fall.

Fire hazards in most houses assume greater danger than structural hazards. Most fires originate under stairs or in closets where old papers and rubbish are stored. There are two "don'ts" that are when observed, homely virtues; "Don't store truck" and "Don't clutter up areas and passageways." The latter is specially appropriate for people who live in boarding houses or tenements. Fire escapes and stairways should always be free from obstructions. Where sleeping rooms do not open on fire escapes they should have fire ropes or chains. Where there are many people in a house there should be fire buckets or fire extinguishers conveniently located. Immediate aid in the beginning of a fire may put the flame out before damage is done. Prevention is better than correction after the damage has been done. Hence the storage of quantities of kerosene, gasoline, benzin, paints, and all inflammable material in or near a dwelling should be discouraged and the practice avoided.

If a house is structurally safe, free from hazardous storage, in a fit sanitary condition for occupancy, if it is a new house and has never before been occupied, it may become a health menace if the number of persons occupying it is more than the house was built to accommodate. Overcrowding rooms brings people in too close contact when there are carriers or cases of communicable disease among the occupants. The hazard comes through the handling of common utensils, but it is especially present when "carriers" or sick persons sleep in beds placed closely together or sleep in the same beds. Even open windows and adequate ventilation are of little avail when too many people sleep in one room. A family too large for its house or one that takes in too many lodgers not only exposes its members but it helps to break down privacy and thus lays the foundation for immorality with its attendant hazards of venereal diseases.

Not infrequently occupancy hazards arise when the home is used for sweat shop manufacturing, for the sorting of old rags, hair, or for chicken killing, or when the bathroom containing a toilet is used for a sleeping chamber, or by installing a cook-stove it also serves as a kitchen. When through force of circumstance houses intended for one family are subdivided into multi-family occupancy, and one room serves for cooking, eating, sleeping, entertaining friends, and caring for the sick, there is a definite injurious effect on family life. Every study of such occupancy has shown increased morbidity and mortality rates with stunted physical development of the children, and an impaired power to labor found in the adults. Occupancy of tall tenements, where compensating improvements have not been installed, has a bad effect on the wife about to become a mother and on the mother who is confined to the house because of the heavy labor involved in carrying the infant up and down the long flights of stairs.

Every householder should make the best possible choice of a future home from the available supply. Select a single dwelling in preference to a two-family house or a tenement apartment. Choose the house with the largest yard but not too large a yard to take care of. Where southern exposure is possible give preference to it. Make certain the house is in good condition, has sanitary equipment, and a heater and is in a good neighborhood. Avoid houses where the plaster has been placed directly on the brick, stone or concrete wall, for as a rule such houses will have damp walls. Keep the house in good condition, make minor repairs, but above all don't injure the property, fixtures, walls or yards by careless use or abuse. When extraordinary repairs are needed notify the owner. If he will not make improvements, move into a better house or notify the local authorities and ask their aid in securing corrections. Join local improvement associations, encourage civic pride and help organize where the town is without it a service for the removal of wastes and the proper care of vacant lots, dumps, streets and other conditions and places ordinarily a menace to public health when left neglected. Through such association encourage your town to make provisions for public health and recreation and to plan for all future developments, so that the mistakes of the past in town growth will not recur in the future. Work for

city zoning to the end that changes in the use of dwellings may not start centers of deterioration in residential areas and develop into future slums.

### Columbia Insurance Course

A comprehensive group of courses covering the field of insurance and related topics, to be conducted by Columbia University instructors in cooperation with representatives of the various large insurance companies, will be given by the department of university extension during the coming academic year. The course on life insurance will be conducted by Joseph B. Maclean of the Mutual Life of New York and that on insurance statistics by Edwin W. Kopf, assistant statistician of the Metropolitan Life.

Mr. Maclean's course on life insurance aims to provide a practical knowledge of the principles of life insurance, and is designed to meet the needs of home office employees, agents or anyone desirous of gaining working knowledge of the conduct of the business. Mr. Maclean will discuss its history and extent, basic principles, actuarial methods, company organization, policy contracts, underwriting, the legal aspects of the business, government regulation, and other allied topics.

Under the general head of insurance statistics, Mr. Kopf will take up the practical methods and concrete results of modern statistics as applied to present day insurance problems. Phases of the subject which Mr. Kopf will discuss include such topics as the administrative control of office and field personnel; production of business; study of operating economies; discovery of new lines of insurance coverage; collection and interpretation of hazard data and risk classification; preventative work; statistical service in modern institutions; preparation of statistical publications, and allied subjects.

The distribution of radium at a remarkably low price to the medical profession is promised as the result of a consolidation of Belgian and American interests effected recently at Brussels, according to an announcement by the Radium Company of Colorado. At a meeting in the Colonial Museum at Brussels, attended by King Albert and 500 eminent scientists, it was disclosed that the Société Generale de Belgique had erected, at a cost of 3,500,000 francs, a plant, which already was in operation, at Oolong, Belgium, for refining radium ores brought from the Belgian Congo.

# Progress In Active Diphtheria Immunization

WHEN diphtheria antitoxin first came into general use in 1895 it was hoped that diphtheria would be robbed of its terrors. Although this hope has to a considerable degree been realized, and the death rate from this disease has been reduced to less than an eighth of its magnitude a quarter of a century ago, the irreducible minimum has not been reached. The fact that the death rate from diphtheria and croup in the Death Registration Area is, at the present time, approximately 15 per hundred thousand, while a source of satisfaction and a proof of the efficacy of past endeavors, should in no way lead to a relaxation in the present program. In spite of the fact that we probably know more about the cause, spread, and methods of control of diphtheria than any other acute communicable disease, there is still room for progress in theory, and still more in practice.

The passive immunity afforded by diphtheria antitoxin is of a transitory sort, hence the satisfaction with which the health worker received the Schick test for determining immunity and the toxin-antitoxin mixture for providing protection of a comparatively permanent nature to non-immunes. A recent contribution to the technic of administering the toxin-antitoxin mixture is of noteworthy importance.

Dr. William H. Park of the Bureau of Laboratories of the Department of Health of the City of New York, whose name is inseparably connected with past achievements in diphtheria prevention, has recently decreased the amount of toxin and anti-toxin administered in the immunizing mixture and finds that the new preparation gives equal protection and has the advantage of causing less disturbance in children of all ages. This advantage is, of course, more important in older children and adults where the reaction is more annoying. In a recent communication to the NATION'S HEALTH, Dr. Park says:

So far as I can judge from animal experiments and the use of the test in a good many hundreds of school children, a preparation which contains in one cubic centimeter, one-tenth of an L plus dose of toxin neutralized by antitoxin to a degree that one cubic centimeter will cause paralysis in two and a half to three weeks, and that five cubic centimeters will cause paralysis and death, will give immunizing results equal to a preparation which contains in one cubic centimeter three or five L plus doses of toxin with three or five units of an-

titoxin. One cubic centimeter of each has the same toxicity in the guinea pig. With the smaller amount of toxin used the proportion of antitoxin is less, that is with the one-tenth of an L plus dose in a cubic centimeter we make the preparation by adding three-eighths or four-eighths of a unit of antitoxin per L plus dose instead of a whole unit. The reason for this is that we would not have the same toxicity if we added the same proportional amount of antitoxin, and also the toxin goes to pieces less in making up the preparation. . . . The advantages of the small amount of protein which the diluted toxin contains are very striking in that the older children and adults have much less local and constitutional disturbance.

I am not quite sure that the one-tenth L plus dose is the absolute final amount that we will adopt as a standard. It may be one-fifth of an L plus dose, but I am sure we will drop to one or the other.

The following summary shows the percentage of Schick positive children remaining immune with the different strengths of immunizing mixtures used.

Preparation	No. Children	Amt. toxin in 1 c.c.	Per cent Immune
48	490	1/10 L plus dose	90
47	304	1/2 " " "	95
50	198	1 " " "	76
44	127	3 " " "	96
46	191	3 " " "	80
41	254	5 " " "	85
45	57	5 " " "	90
42	176	5 " " "	83

A comparison of the large and small doses in respect to the amount of reaction shows:

	1/10 L plus	3 and 5 L plus
No reaction	25%	0%
Slight reaction	64%	41%
Moderate reaction	11%	37%
Marked reaction	0%	22%

In the 22 per cent showing marked reaction to the large doses, 6 per cent were classed as constitutional reactions.

At the present time about 280,000 school children in New York City have been Schick tested and immunized whenever necessary. This figure is about 40 per cent of the number of children who have received circulars and consent slips with the request that testing be permitted. The same procedure has also been carried out on about twenty thousand children of pre-school age. There have been no accidents and during the past two years the death rate for the city has dropped from 21 per hundred thousand to 16.

The New York City Health Department now employs a force of ten physicians, eight nurses, and eight clerks for the Schick testing and immunization of school children. With this force it is expected that by January 1 all the public schools will have

been covered and that by June 1 all the parochial schools will also be finished. The city has appropriated in the new budget funds sufficient to make permanent a diphtheria force of five physicians, five nurses, and five clerks. When the present school population has been tested and immunized, which will in all probability be accomplished this year, it is thought that the permanent force now provided for will be sufficient to immunize the entering scholars and to make available similar benefits for all children of the pre-school age that can be persuaded to attend the Baby Health Stations.

The accomplishments in Auburn, N. Y., show what results may be expected from a similar campaign in a smaller city. Auburn is a progressive city of about thirty-six thousand population, with a school population, including parochial, of about seven thousand. During the last ten years diphtheria has been increasingly prevalent in this city. Soon after the opening of the schools in the autumn of 1921 it became apparent to the school physician that a mild unrecognized epidemic of diphtheria had existed in the previous summer months in the Polish and Italian sections of the city. The pupils of one entire school of 700 children were cultured. Nearly 45 per cent of the cultures were positive and many of those tested were virulent strains. Early in February of this year a campaign for immunization was begun under the direction of Dr. Frederick W. Sears, the county health officer. Consent for testing and immunization was secured for about 4,200 of the seven thousand children in school. About 2,400 of these gave positive Schick reactions and three immunizing doses were given to 90 per cent of these. No unfavorable results were encountered from either the tests or the immunization. The work was completed in the middle of March. From May 8 to June 9 there were no cases of diphtheria under quarantine in the city of Auburn. In September Dr. Sears had the opportunity to retest about 1,400 of the children who were positive the previous spring. About 65 per cent of these showed an absolutely negative result, and of the remaining 35 per cent about 20 per cent showed a very slight positive reaction. There were very few that showed only a typical positive reaction and it is believed that had the re-Schicking been delayed two or

three months most of the 35 per cent would have become negative. The work in this city shows that it is not necessary to secure 100 per cent immunity and that the reduction of the non-immunes in a community to a small percentage is sufficient to secure control of the disease. In a communication to the *NATION'S HEALTH*, Dr. Sears says in regard to the administration of toxin-antitoxin for the production of immunity, "from the results which I have seen I feel thoroughly convinced that it is the only practical method for the control of diphtheria."

Dr. F. X. Mahoney, Health Commissioner of Boston, writes that work in their city health department was started in May, 1922 and that they "feel very much encouraged at the reception of this work by the public." Nearly twenty thousand Schick tests have been made and about half of the positive reactors have been given three injections of toxin-antitoxin. School health work in Boston being in charge of the Board of Education, the health department has limited its work to the pre-school child, inmates of various institutions, and children in the parochial schools.

The cities here mentioned are not

the only ones that can be cited in support of the contention that toxin-antitoxin immunization should be a routine procedure in every school in the country. In view of the lack of all health work in many rural communities it cannot be hoped that this will be accomplished at once. It is not, however, beyond the bounds of reason to urge and expect every city and town that does support medical school inspection to give this problem serious thought. It seems quite certain that no point of attack will permit greater achievements in proportion to time, labor, and money expended than will the use of the toxin-antitoxin mixture in preventing the ravages of diphtheria in the schools.

There has been little fault found with the use of the stronger mixture that has been in general use up till now. Additional refinements are none the less welcome. Dr. Park's contribution in demonstrating that a smaller dose may have equal immunizing powers with no danger of marked reaction to the foreign proteins injected removes the last possible objection and diphtheria should rapidly approach, though it will probably never reach, the extinction where now rests the Dodo.

been brought about between the manufacturers and biological laboratory workers, at present practically the entire needs of biologists in this line can be supplied by domestic products.

The investigation which has brought about these results is one of the most extensive pieces of cooperative research that has ever been organized in this country. It began through the efforts of the Society of American Bacteriologists to obtain satisfactory stains while deprived of the German supply. Realizing that the matter was not a special bacteriological problem but was one of much broader interest, this society called in the assistance of other biological societies and finally through the assistance of the National Research Council, cooperation was secured of all the organizations considered to be especially interested in such problems. Members of the respective societies were addressed in circular letters and in this way the biologists most interested in biological stains were located and they have been actively cooperating with the committee appointed by the Research Council. The collaborators thus secured number nearly one hundred, and at the present time a permanent commission on the standardization of stains has been formed which is to be composed of all those of these collaborators who care to be on it. This means the continuation of the work in the future.

Such an investigation as this, of course, requires a certain amount of money to keep it going. Fortunately, most of the work has been voluntary; so a great deal has been accomplished at a comparatively small expense. Nevertheless certain expenses were unavoidable and when the investigation was begun it was hampered from lack of resources. The scientists interested in the matter could not afford to finance it themselves, and the business in stains is not a sufficiently profitable one so that the expenses could be charged to the industry. To relieve this situation the Chemical Foundation kindly offered to finance the work and up to the present time its continuation is dependent upon this support. The work is still far from complete, but more and more important results are being obtained all the time. The progress so far made is very gratifying and promises that the future will bring about a much better situation in regard to stains, both as to quality and availability, than existed before the war.—H. J. CONN, Chairman.

## Health in the Dye Industry

BY H. J. CONN, CHAIRMAN, COMMISSION ON THE STANDARDIZATION OF STAINS, NEW YORK CITY.

ONE small but rather important phase of the dye industry is the production of stains used for biological purposes. This is important because their use for this purpose has a distinct relation to public health. Stains are used in the bacteriological laboratory for the diagnosis of several diseases such as diphtheria, tuberculosis, typhoid, malaria and several others. They play an important part in the examination of milk to determine its sanitary and keeping qualities. When diseased tissue is examined in the case of some unknown disease, stains are absolutely necessary in order to learn what pathological conditions exist, as for example in examining tumors that are suspected to be cancers. They are, moreover, absolutely indispensable to the investigator who is obtaining new knowledge concerning the nature or cause of any disease.

The stains used in this work are in many cases dyes that are also widely used in the textile industry. In other cases they are special dyes that perhaps have never been used

for textile purposes, or if they have been so used in the past they have now been replaced by other dyes that are more practical for dyeing fabrics, and are, therefore, obsolete so far as concerns the textile dye industry.

Before the war biologists were absolutely dependent upon Germany for all of these stains. Not only were the basic dye manufacturers located abroad, but the only concern which specialized in biological stains was in Germany. This is a very highly specialized line of business requiring a knowledge and technic which the ordinary dye manufacturers do not have; and as only this one concern developed this line before the war, the whole world was dependent upon it for biological stains.

The exclusion of German products during the war not only stimulated the dye industry in this country but caused certain new concerns to be formed in America which made a specialty of biological stains and closely related products. At first their stains were not wholly satisfactory but, thanks to the cooperation which has

# The Medical Inspector On the Open Road\*

## Maryland Rural Children Welcome Itinerant Public Health Doctor

By E. BLANCHE STERLING M.D., UNITED STATES PUBLIC HEALTH SERVICE, BALTIMORE, MD.

THERE were three thousand throats to be inspected, twice as many eyes to be tested, and many times three thousand teeth to be examined. Besides these, there were all the other items of a routine medical inspection, the weights and measurements, and the special examinations. Altogether, it was enough work to last several months since it was scattered over a country with only the usual supply of good roads.

This particular county was one of the most beautiful in Maryland, with rugged hills, gently-rolling farm lands, long stretches of woodland, and several rivers making their way to the Chesapeake Bay. Scarcely a dozen settlements were large enough to be called towns. Almost seventy-five per cent of the schools were of the one-room type. As in every country district, many of these little schools were pitifully inadequate in construction, in equipment, in conveniences, in hygienic requirements, and sometimes even in ordinary comfort. Each, however, housed its quota of the approximately four million children in the United States who have no better schools to go to.

The superintendent turned me over to the supervisor, with the courteous assurance that she would assist me in any way possible, which she undoubtedly did. Her hearty cooperation,

\*Approved for publication by the Surgeon General.

clear vision, and sense of humor made her the sort of co-worker one devoutly prays for, but scarcely dares hope to obtain.

The school I began in was about as far removed from the ordinary little one-room rural school as one can imagine. It was a beautiful modern building erected during the war by the Federal Government on the Government Reservation. Medical inspection here was a simple matter, with a private office where each child could be taken separately for its examination. It was only when I fared forth into the county that anything like expert management was required.

Comparatively few of the county schools could be reached by railroad, and one of our means of transportation was an open Ford car with no self-starter. That car was the means of bringing to light the real chivalry of the men and boys of the county. It was cranked by all of them, old and young alike. In all sorts of mishaps, from dangerous skidding on the icy highway to running out of gasoline on a lonely, muddy road, there was always one to the rescue. When ice or snow made motoring risky, we visited schools in the railroad towns. I shall never forget the helpfulness of those Pennsylvania train crews. A medical inspector cannot travel light. A suitcase full of the paraphernalia of examination, scales for weighing, and a Boston bag furnished consider-

able impedimenta. However, one can manage quite well with an obliging conductor or brakeman to lift them on and off the trains, and some husky schoolboys as transports between school and station.

When the spring thaws set in, there were certain roads in the low-lying "necks" of land between the rivers where the seas of mud made one shudder at the thought of driving an automobile. Then we took to the open road with a horse and buggy. Driving in this fashion through lovely woodland roads in the Maryland springtime to little far-away schoolhouses full of children from farm and village—this is a thing to hold in one's memory to a green old age.

Medical inspection was new in this county, and neither children nor grown folks knew quite what to expect. Country school children have few visitors. Not many people come in from the outside to do anything for them, and hence our arrival always aroused an intense interest. They had heard of this new thing, and were often a little awed, or dubious, or shakey, at first. But by the time we left a school the children generally had had as good a time as the supervisor and I.

The procedure in each school was practically the same, though of course it was sometimes modified to suit particular circumstances. The ice was usually broken by appealing to the child's desire to do something. The larger boys were asked to bring in the suitcase and scales. Practically all children old enough to go to school are interested in their weight, and the appearance of the scales gave them something pleasant to look forward to. The Junior Red Cross had paid for those scales and the children had a proud sense of ownership.

Before the examination came the history taking—filling in the name, age, sex, grade, previous illnesses, etc., of each child on his examination card. In large schools this can be done beforehand by the teacher or assistant, but these little schools are too widely separated to make an extra trip with the cards practicable. It did not take long here, the inspector and nurse or supervisor being often assisted by the

In the early spring when country roads are almost impassable, the medical inspector abandons her motor vehicle for an earlier and surer mode of transportation.

Over the open road, the inspector travels, by horse or motor, a symbol to the Maryland rural school children of their country's interest in their welfare.

teacher or some visitor. Sometimes an older brother or sister can supply information impossible to obtain from very little ones. In taking these histories we sat in the school seats with the children, making friends with them as we went along.

When the cards were ready, the children stood in an orderly line, and each walked up alone for his individual inspection. Only very rarely does a child object to this examination. Their little mouths often fly open before you are ready to inspect their throats. There are several things to be done before the tonsils are arrived at. Lameness or deformity should be noted as the child walks towards the inspector. Orthopedic surgeons do not, as a rule, set up offices at country crossroads, but follow-up work may be able to start the parents on the way to find one. A country mother does not want her child to grow up crippled or deformed any more than a city mother does, but it is much easier for the latter to find means of preventing it.

Every child is inspected for the presence of contagious eruption on the hands or face. Indications of the presence of adenoids must be noted, as well as enlargement of the glands of the neck. Very important is the examination of the eyes to detect signs of trachoma which, if not treated, may result in total loss of sight. Finally, the tonsils and teeth are inspected, and the child goes to his seat, the next one in line taking his place.

By the time this part of the examination is over, we are all pretty well acquainted, and ready to enjoy the weighing and measuring to the last ounce and inch. When the order "Take off your shoes" is given, one of the real thrills of the whole wonderful adventure is felt, and an excited little shuffling takes place. Occasionally, a boy has on heavy top boots which he can't get out of without the help of a bootjack. Since neither school commissioners nor medical inspector has had the foresight to supply this important article, the boy has to be weighed with his boots on. But he gets weighed just the same, and the fact that he is booted is entered on his record. No country child is going to suffer the disappointment of not being weighed simply because he can't fulfill some technical requirement.

In addition to their height and weight, older boys are much interested in their chest measurements. I have had high school boys come back to try to add an extra fraction of an inch to their chest expansion on hearing that some other boy had made a better record.

Testing the vision by means of the Snellen charts is a simple matter, but the tests for defective hearing and the Binet-Simon tests of intelligence are not easy to manage in a one-room school. These are difficult because there is no place (in winter) where you can get the child alone and quiet, with nothing to distract his attention. On a warm spring day the child of suspected mental defect can be taken out of doors and tested there. If done in the schoolroom, I would take the child to the rear of the room, while the supervisor would gather all the little restless people up front and tell

them a story in soft, low tones.

The further examination of those children who seem to need it can be easily arranged in a one-room school. If there is a vestibule and it is not too cold, that will answer, but a warm vestibule is a luxury not often found in the country. We used to carry an ordinary bed sheet in the suitcase, and the nurse would hang this on a cord stretched across a corner. This was not a bad examining room, even if sometimes there was no way to write down your records except by holding the card up against the wall. Sometimes a recess period was utilized for this purpose. When the children had all gone out to play, the "specials" were sent, one at a time, back into the schoolroom for a more extended examination.

When everything was finished, we would pack our things away in that battered old Government suitcase, the boys would lift it and the scales into the car, crank up, and we were off. Of course the supervisor took advantage of these visits to look after her own job, and one medical inspector learned something of rural school teaching that year.

### The Human Side

Probably those children of the Maryland farms and villages were much like other country children, but they seemed like very special children to us—just like your own children seem to be different from other people's children. There was chubby, fascinating Grace Louise who especially requested that she might be the first child examined in her school; and dainty, adorable Ruth who held up the whole line while she threw her arms around me. These were very little pupils, but they were no more

These curly little ruffians take kindly to the physical examinations, one youngster having trailed the doctor for several miles demanding he be tested.

Dating back to ante-bellum days this deserted "little red schoolhouse" is one of the type fast disappearing.

charming than the lovely "big girl" who at lunch time prepared the small girl's orange so that it could be eaten easily and daintily. This was just a bit of that helpful "family spirit" sometimes found in these little schools. I am sure I was never the recipient of a more chivalrous kindness than that shown by two gallant high school lads who stood out in the cold mist of the worst sleet storm of the winter and worked for ages trying to start the engine of that cold, stubborn, cranky, old Ford.

In one school a small boy gave me a York Imperial apple, and I had it made into a pie. Then I wrote the child a letter on Government stationery, telling him how good the pie was. That boy and all his kinfolds know that the United States Public Health Service is made up of just everyday folks who like apple pie. Then there were the pretty twins and the little girl whose "grandmother said if her tonsils had to be cut they were going to be cut"—all three of whom insisted on staying out of their class a large part of the time in order to help me. I was sorry I didn't have enough things they could do.

I think I did one absolutely unprecedented thing in school medical inspection that year. We had driven to a little school that day in a buggy, the supervisor and I. Before the spring thaws began, my nurse was providentially removed—not to a higher sphere, only to Missouri. I say providentially, because when a suitcase, scales, two personal bags, and two women, not to mention provender for the horse, are packed into a buggy there is no room for another person. If we used a heavier, two-seat vehicle we were apt to get stuck

in the mud. On the spring day in question we had all our paraphernalia stowed snugly away in the buggy, and were just leaving the school when a fine looking boy about twelve years old rode up on a bicycle. He explained that he had not been able to get to school early that day because of certain home duties. We expressed polite regret that he had not been present for the examinations, and drove off. We jogged along past a farmhouse, a little beyond which the road crossed a stream. I always carried a kodak, and we stopped here to get some snapshots. While the supervisor was posed on the bridge unsuccessfully trying to conceal the fact that she had no relish for this part of the job, the boy on the bicycle appeared in the left foreground.

"Mother said would the doctor come back and examine me?"

The supervisor and I exchanged harrowed glances. Doubtless she was thinking, as I was, of all those goods and chattels so carefully packed away in the buggy. But here was a boy who wanted the examination, and back there in the farmhouse was the mother who had sent him after us. We went back. In the farmhouse kitchen, with its basket of downy, new-born chickens close to the stove, and pats of yellow, new-made butter on the table, the boy had his examination. The kitchen was too small and dark for the vision test, so we tacked the Snellen card to a pillar of the porch, measured off twenty feet on the ground, and tested the boy's eyes out of doors.

We often invited people to the schools on the days of the examinations. We took the Johns Hopkins professor two or three times; and the country minister, with a boundless

zeal for service, was a helpful visitor to the schools in his parish. We were especially glad to have the country people come because we wanted to take them into our confidence in this matter, to show them that the medical inspection was just a friendly way of helping their children by learning their needs. I have had a plump little grandmother sit behind the bed-sheet screen with me, giving helpful information about the children who needed special attention. Young mothers have done the same.

At one school, the mothers were invited to come to the schoolhouse at the close of the afternoon session immediately following the examinations. The rain came down in a flood that day, but some mothers managed to get there in spite of it. The teacher served tea, and I talked to the women individually about their own children. In other cases after the physical condition of the child was ascertained, the parent was notified of the defects discovered.

Officially, this work was an investigation of the health conditions and needs of rural school children. In addition, it brought Uncle Sam very close to a most attractive and appealing set of nephews and nieces, the children of the open spaces.

### Advance in Local Care of Dependent Children

The most recent administrative advances in the local care of dependent, defective and delinquent children are described in a report recently issued by the United States Department of Labor through the Children's Bureau, entitled "County Organization for Child Care and Protection." Administration of care for neglected, handicapped, or delinquent children by local boards of citizens, employing trained workers and aided by state boards, is, according to the report, the plan which is gaining approval in a constantly increasing number of states.

Within recent years laws requiring or permitting some form of county welfare organization of broad scope have been passed in Arkansas, Minnesota, Missouri, North Carolina, and Virginia, while individual counties, private agencies or state boards in Alabama, California, Florida, New Jersey, Pennsylvania, and South Carolina are working out similar plans without special legislative action. County organization concerned mainly with the care of dependent children is found in Arizona, Indiana, New York, and Ohio.

# Control Measures in Reducing Contagion\*

## Proper Supervision Will Cut Children's Diseases to Minimum

BY LOUIS OLSEN, CITY HEALTH OFFICER, PALO ALTO, CALIF.

THE effectiveness of the modern health department is still measured largely by its success in the control of communicable diseases. Notable results have been attained along these lines in the control of certain diseases, such as typhoid fever, yellow fever, malaria, and even tuberculosis. A steady reduction is also noticed in infant mortality.

Remarkable as have been the reductions in mortality from the above mentioned causes, the same success is not apparent in the figures for some of the common contagious diseases of children. An examination of the death rates in California from scarlet fever, diphtheria, measles and whooping cough shows that the rates for 1921 are practically the same or greater than the corresponding figures for 1911. In the intervening years the rates have fluctuated, always many deaths occurring from these co-called harmless diseases. In 1921 there were 117 deaths from scarlet fever, 614 from diphtheria, 127 from measles and 191 from whooping cough, while only 147 deaths were caused by typhoid fever. During this year also, the combined number of deaths from scarlet fever, diphtheria, measles and whooping cough (1,079) was greater than the combined deaths from typhoid fever, malaria, smallpox, influenza, dysentery, poliomyelitis, encephalitis and epidemic meningitis (847). The latter total could almost include the venereal diseases (422), and still be less than the four children's diseases mentioned above.

These statistics, it must be remembered, are for immediate deaths only, and take no account of the long list of sequelae that follow. In measles alone it is estimated that there are ten cases left with serious complications that may later result in death, for each death reported. Investigations now being conducted will almost certainly show that many other serious complications of adult life are to be attributed to these communicable diseases of childhood. In the face of such figures it may be well

to consider whether or not health officials are spending their energies entirely in the right direction. May it not be time to place more emphasis on communicable disease control and particularly control of some of those that are often laughed at and treated jokingly?

In presenting the subject of proper control measures it is not planned to advance any new theory or discovery that will stamp out these diseases. Perhaps there are some who are waiting for such a new discovery in the hope that a quick and easy way will be found as has been the case with yellow fever and malaria. The history of the last ten years proves that a specific remedy is not always all that is necessary. Diphtheria, in spite of anti-toxin and the Schick test, is with us still. The purpose of this paper is rather to outline a general plan of procedure, regardless of the specific remedies that are to be employed for each particular disease, a plan of procedure that has been known for a long time and that has been proved by experience to be effective.

### Reporting of Contagion

The modern theory of infection removes public health activity from the realm of speculation and places it upon a definite and exact basis. When it was discovered that communicable diseases are caused by specific organisms which are transmitted from person to person and that cases never arise spontaneously, the health worker had a sound foundation upon which to build. Control then became a matter of finding the infected persons and controlling the infected discharges for the purpose of preventing their being transferred to other persons. This underlying principle of control is as true today as ever. It matters not that the causative organism is not known for all of the diseases mentioned. They can be controlled by breaking the cycle whereby discharges from the infected individual are transferred to the uninfected individual.

Two characteristics, of such importance as to be almost cardinal virtues, in executing any plan of con-

trol are speed and thoroughness. These must be applied to every step hereafter mentioned. If they are, results will follow. A good motto for disease control is, get the first case; get every contact; prevent additional transference of infected material. The procedure in effecting proper control of communicable diseases may be separated into four steps, as follows: (1) reporting; (2) investigation; (3) institution of control; (4) release from restrictions. The steps are mentioned in the order in which they will be undertaken and in the order of their importance.

It has been often said and written that "No health department can effectively control communicable diseases without first knowing when and where cases are occurring." No statement was ever more true and an effective and complete system of securing reports is the first requisite. Before discussing the methods of obtaining reports, it may be well to state that reports minus speed are about as usual as a football team without speed. Reports by mail, in cases of scarlet fever, diphtheria, measles and whooping cough are too slow. They should be reported by telephone immediately, in addition to the written card.

Reports will ordinarily first come to the health officer from the local physicians. It is of the utmost importance that the health officer shall have the confidence and cooperation of the physicians in his community, otherwise the difficulties of disease control will be insurmountable. It will be found that if the health officer is reasonable the physicians will be more than ready to do their share. Granting that the physicians desire to report, cases may sometimes be forgotten and schemes to prevent this are necessary. It has been found that a weekly summary of the morbidity situation, mailed to each physician, stimulates interest and keeps them informed as to what diseases are in existence in the community.

Not all cases will be attended by physicians and the health officer can not depend upon physicians' reports alone in combating an outbreak. This is particularly true of those

\*Read at annual meeting of California Health Officers held at Stanford University, September 19 to 21, 1922.

diseases whose seriousness has been so much underestimated. The following figures illustrate this point:

health officer's work made correspondingly easier.

Having received the report of a

FIVE YEARS OF CONTAGIOUS DISEASE IN PALO ALTO

	Cases	Physician	None
Chickenpox	289	89	200
German Measles	353	31%	69%
Measles	383	156	197
Mumps	170	44%	56%
Whooping Cough	187	222	160
		58%	32%
		75	95
		44%	56%
		120	67
		64%	36%

The thing to be emphasized is that the physicians see only a fraction of the total cases, and without systematic search for the discovery of every case and suspected case, no matter what the conditions, it is almost useless to work with the small percentage seen by them. It may also properly be mentioned here that comparisons of the numbers of cases reported in different cities are misleading and lead to wrong conclusions for the reason that the city that is actively and intelligently combating disease will get reports of all or nearly all of its cases, while where no active work is undertaken the number of cases will represent the physicians' reports only.

The largest number of reports of cases unattended by physicians will be obtained by the public health nurse. Such an officer, in investigating absences from school due to illness, will pick up most of the cases in children of school age. If the school teachers are properly instructed in reporting all illness they will sometimes note cases even before they are seen by the nurse. The teacher need not be a diagnostician, but she should know enough to exclude from the classroom and hold for observation every child having any symptoms whatsoever. By this is meant even the "common cold" which in many places is permitted to run along unnoticed.

The getting of reports of cases among children of the pre-school age unattended by physicians presents the greatest difficulty. These reports are particularly important because children of this age are not under constant observation as are children in school. Clues and hints as to cases will come from neighbors, children in school, and others. Each such report must be investigated, no matter how unpleasant the task may be. A single missed case may do untold harm. The subject of reporting must not be concluded without stating that there are many parents who report promptly themselves. By proper education this group can be enlarged and the

case, the responsibility then rests with the health officer. Here, again, speed is required. The investigation must be commenced at once, not on the next day or on Monday. Every case, whether real or suspected, should be investigated. It is not enough simply to make a record for the office and perhaps placard the premises. Before commencing the investigation the officer should be equipped with cards or other suitable means for recording the results obtained.

In making the investigation the house or premises should be visited, a list made of all persons in it, together with their occupations and whether or not they may be immune to the disease. All persons who have been in contact with the case since the commencement of illness should be listed. As much information as possible bearing on the case should be obtained and recorded. Inquiry as to the probable source and the whereabouts of the patient on the date that the infection was probably acquired should be obtained. The determination of the source, if possible, is important and sometimes constitutes an interesting piece of detective work. Sometimes the source will only be determined after a number of cases have been investigated and the data obtained tabulated and studied.

Where there are many cases and careful and complete records made of each one, the outbreak can usually be diagrammed and studied, information often being obtained that will be of use should another similar outbreak occur.

Laws will usually govern the control proceedings. However, laws alone will not control or prevent diseases. The personal element is exceedingly important and a good health officer will accomplish more with poor and insufficient laws than will a poor officer with the best laws and regulations in the world. The best regulations for the control of communicable diseases are those that accomplish the prevention of spread of the infected

material with the smallest amount of interference with the regular routine of the family affected. Modern regulations have this tendency and therefore receive better support from the public. The main burden will fall on the household where the case exists, provided it is not taken to a hospital. Control must not stop here, however. Every contact or exposure must be watched until the maximum period of incubation has passed. Where the exposure has been limited to a certain day and is definitely known, the restraint placed upon the contact may safely be limited to a few days covering the period when the disease is expected to appear.

In this, the last step, speed is not so necessary, although there is no reason for restricting the case after the period of infectivity has passed. The determination of the proper time for release will differ with the several diseases and need not be discussed here. The principle is the same for all, i.e., when the danger of spreading the infected discharges has passed, release them. Contacts who pass over the maximum period of incubation without developing the disease should of course be released without further ceremony. Cases should never be returned to school without a written permit from the health officer. A good plan is to require all school absences of more than a day or two to have such a permit before returning. This usually removes the last opportunity of concealing a case in a school child.

The question about fumigation may be asked. The answer is, disinfect, but do not fumigate. Nothing more need be said about disinfection than that it should be carried on concurrently with the course of the disease, and at its termination should consist of a good, honest, mechanical cleansing of the infected area. About the only time to fumigate is in the case where the householder thinks this method is the last word in perfection and where you see that it is useless to try to change his mind. After he has fumigated to his heart's content insist on a final cleansing and scrubbing.

In general it may be stated that marked success has attended the efforts of health workers in controlling diseases where some one discovery was all that was needed. The same success has not been had with those diseases that for the present can only be controlled by painstaking attention to detail. The whole plan for control is dependent upon speed with quick and thorough action.

## Chlorination Prior to Filtration

The water supply of the city of Toronto is filtered by means of slow sand and drifting sand systems at a plant situated on an island at a distance of two miles from the city. From the island the water flows by gravity to a point one mile north; drops down a vertical steel shaft to a tunnel 90 feet under Toronto Bay, and flows by gravity to the city where chlorination is effected before distribution. The unusual location of the plant and the possibility of leakage between the works and the city are the reasons for not chlorinating immediately after filtration.

The plant was designed to operate with alum applied at the rate of 1 grain per gallon. Increased pollution of the water made it necessary to increase this amount to as much as 2.5 grains per gallon in order to secure a satisfactory effluent. The cost of treating from 35,000,000 to 50,000,000 gallons per day by this method involved an enormous expense and at the same time the increased dosage of alum cut down the capacity of the plant. It was found during the summer months that chlorination before filtration when applied in amounts up to 1.5 grains per gallon, was more effective than alumina sulphate in reducing the bacterial content. In the winter months alum compared more favorably with the chlorin.

The only objection raised to a double treatment with chlorin was that it would accentuate the taste in the water that appeared at certain times of the year, particularly when easterly winds prevailed. For a time chlorin and alum were used alternately depending on the prevailing physical and meteorological conditions. Later chlorin was applied continuously.

Before this time the capacity of the plant was seriously taxed during the summer months but with the use of chlorin the rate of filtration was increased from 150,000,000 to 175,000,000 imperial gallons per acre per day.

The percentage reduction of bacteria growing on agar at 37 to 39 degrees centigrade with 24 hours incubation was, including all the results of the year, 95.2. When alum alone was used the reduction was 93.6 per cent, and when chlorin alone was used the figure was 96.3.

The figures for reduction in excremental bacteria grown on bile-salt agar with the same incubation were 93.8, 91.1, and 96.9, respectively. The indicated number of *B. coli* were re-

duced 99.8, 99.6, and 99.9 respectively. Whatever the method of bacterial count the figures consistently show that the chlorin treatment produces better results. Happily this is also accomplished at less cost. In 1920, 1219.26 tons of alum were used at a cost of \$60,963.00. In 1921, when alum and chlorin were used alternately, the former cost \$18,155.00 (363.1 tons), and the latter \$2,345.37 (9.373 tons). Although additional labor was necessary under the latter method which amounted to \$5,975.32 a saving of \$34,489 was effected.

This interesting means of obtaining purer water at less cost and at the same time increasing the capacity of the filtration plant is reported at some length by Norman J. Howard in *The Journal of the American Water*

*Works Association*, July, 1922.

A census of typhoid carriers has been taken during the past twelve months by the bureau of preventable diseases of the New York City department of health with the following findings: Forty-four chronic carriers in Manhattan, 10 in the Bronx, 34 in Brooklyn, 14 in Queens, and 4 in Richmond. A definite set of rules was also formulated and made public for the regulation and supervision of these health menaces. The rules warn against the handling of food, and urge the carriers to practice scrupulous personal cleanliness, to use individual plates, towels, etc., and separately washed, and to keep in touch with the department. Members of the family and close associates of the carrier are urged to take immunization treatment.

## Vital Index of England

AN interesting study from the Department of Biometry and Vital Statistics Johns Hopkins University, on "The Vital Index of the Population of England and Wales" appeared in the proceedings of the National Academy of Sciences, April, 1922. Using the term vital index to indicate the ratio births per 100 deaths in a population, Raymond Pearl and Magdalen H. Burger have analyzed the biological fitness of England and Wales from 1828 to 1920. By means of this demographic function if the vital index is greater than one hundred the population is not only surviving but growing, whereas if less than one hundred the population is starting on the road to elimination.

The data have been computed for each quarter of the eighty-three years covered by the study but the accompanying figure, plotted on an arithlog grid, tells the whole story at a glance.

The steady increase of the vital index for more than three-quarters of

Trend of vital index (100 births/deaths) and crude birth rate in England and Wales, 1828-1920, inclusive.

a century shows that the population of England and Wales has more than reproduced itself. Influenza and war have been the only influences sufficiently powerful to effect the slow but steady rise in the vital index. Perhaps the most striking feature of all is the rapid return to normal or nearly normal that followed the war and the recent influenza epidemic. The gloomy view that the trend of British people was biologically downward had its foundation solely on the fact that since the quinquennium 1875-1880, the birth rate in England and Wales has been falling rather rapidly.

From a purely biological point of view the writers ask: "What matters a falling birth rate if the death rate falls even more rapidly, so that the net survivorship at any instant of time is constantly getting higher?" It is realized that it will be answered that nowadays the "best" people do not produce their due share of progeny, while the "worst" people overproduce, but the social and eugenic aspects of the problem are not capable of measurement by this means. It is a debatable question whether old Dame Nature is interested in any test of "best" and "worst" except survival, though Pearl has previously shown that the vital index of the American negro is generally less than one hundred. The interest of this study is purely biological and is remarkable in the extraordinary perfection, demonstrated in the figures, of the self-regulation of population growth.

# Digest of Sanitary and Hygienic Advance

THE administration of iodids in food in goitrous regions has received recent consideration. Lack of iodids being a food deficiency, Hirschfelder (*J.A.M.A.*, Oct. 21, 1922) advocates, as the simplest and easiest method of supplying the deficiency, the use of iodized salt. The procedure suggested is as follows: First a stock of iodized salt is prepared by spraying or sprinkling one pound of ordinary salt, spread in a large tray, with 50 c.c. of 10 per cent solution of potassium iodid in 60 per cent alcohol. After securing as even a distribution as possible, the salt is well stirred, slowly dried by evaporation over a water bath or on the top of an oven, and ground in a mortar or crushed with a large spoon. This stock may be used for iodizing all the salt used or for the salt used on the table only. In the former case five pounds of salt are spread on a large surface and five tablespoonfuls of the stock iodized salt sprinkled over it by means of a shaker and the whole thoroughly mixed. In the latter case, on the assumption that from one-fourth to one-third of the salt ingested comes from the table shakers, the table salt should contain four times as much. Such a mixture can be secured by adding two tablespoonfuls of the iodized stock to each pound (two large cupfuls), or half a tumblerful to a five pound sack.

De Quervain *Schweiz. med. Wchnsch.*, Aug. 31, 1922) also advocates the use of iodized salt by prospective mothers as a preventive of congenital goiter, but cautions against its indiscriminate use by children approaching the age of puberty. Bircher (*Ibid.*) urges the need of scientific control of the administration of iodine, stating that any exaggeration in the basal metabolism forbids its use.

## The Hazard from Consumptives

Gloyne (*Tubercle*, Aug. 1922, p. 497) has attempted to answer the following questions: (1) Are virulent tubercle bacilli commonly present in the mouths of patients suffering from pulmonary tuberculosis? (2) If so, can these organisms be transferred to table utensils? (3) Does the washing of these utensils destroy the bacilli?

The mouths of twenty patients, ten having much sputum and ten having scanty sputum, were washed with 40-50 c.c. of sterile water plus 0.5 per

cent antiformin to destroy the secondary organisms. The centrifugalized deposits were inoculated into guinea pigs. Of the ten cases with much sputum eight gave positive results and of the ten cases with scanty sputum two were positive. Similar tests relative to the spoons used by the patients were entirely negative in the group with scanty sputum and 60 per cent positive in the group with much sputum. No infective material was found on other utensils and the ward cooking was negative. Gloyne concludes from this that patients with profuse sputum are the more infective and that plain water is a satisfactory sterilizing agent for tuberculosis hospitals.

## Diagnostic Test for Pertussis

In a preliminary report (*J.A.M.A.*, Oct. 28, 1922) there is much promise of a valuable method for the diagnosis of whooping cough during the incubation period and the catarrhal stage. Oregel reports the use of a vaccine of *Bacillus pertussis* containing two billion bacilli per cubic centimeter. Two minims of this vaccine were injected intradermally into one forearm of the patient to be tested and two minims of steril saline solution in the other forearm to act as a control. Positive reactions usually appear as slightly raised, coppery red, circular areas at the site of injection. This area appears about the third hour, increases in size up to the sixth, and from then on a gradual recession of the erythema takes place leaving a slight area of induration which lasts about a week.

The reddened areas vary in size from 5 to 25 millimeters; those under 5 millimeters in diameter being considered negative. The groups used were small but carefully controlled and the results strongly indicate an accurate and valuable test.

## Diagnostic Value of the Sachs-Georgi Test

The results of parallel Sachs-Georgi and Wassermann reactions on 1,748 specimens of blood serum have shown a total agreement in only 85.5 per cent of the tests. Of the positive Wassermans, 33.3 per cent were missed by the Sachs-Georgi test and 26.5 per cent of the positive Sachs-Georgi reactions were not confirmed by Wassermann tests or clinical findings. These findings are reported by

Craig and Williams (*J.A.M.A.*, Nov. 4, 1922). The Sachs-Georgi reactions were read by one of the authors and the Wassermann reactions by the other, thus obviating any unconscious, erroneous correlation in the doubtful reactions. The authors conclude that the Sachs-Georgi test cannot be relied on alone. Kilduffe (*J. Am. Med. Sci.*, Oct., 1922) reports a similar study of 430 tests combined with a previously reported one of 296, stating that non-specific reactions in the Sachs-Georgi test make it unreliable.

## Fallacy of Yeast Therapy in Infant Feeding

Because yeast can be successfully substituted for part of the protein requirement of an adult, is non-toxic, will apparently improve skin diseases in adults, cure polyneuritis in pigeons, and cause rats on an inadequate diet to gain in weight, numerous claims have been made that yeast in various forms is a panacea for all the ills of man and that even infants would be improved by a tablet or two a day.

Davison states (*Am. J. Dis. Child.*, Oct., 1922) that this conclusion is falsely derived from unapplicable premises and is not proved by the elementary rules of logic, but, furthermore, experiments have shown that, when applied to infants, yeast therapy is not only without benefit but may actually do harm. The author reports a small series of cases from which he concludes, in substantiation of the previous statements, that the administration of yeast to patients convalescent from acute intestinal indigestion (6 patients), to infants suffering from chronic intestinal indigestion (3 patients), and to a physically retarded child (1 patient), is without benefit and may possibly do harm.

## Food Requirements of Children

Holt and Fales (*Am. J. Dis. Child.*, Oct., 1922) find from theoretical consideration and from practical observation that a diet in which the fat supplies 35 per cent of the total calories, the protein 15 per cent, and the carbohydrate 50 per cent, is the one which meets the nutritional needs of the child after infancy. It is one which is well borne by the digestive system, and may be considered a well-balanced ration. The observations were made on a series of 106 children between the ages of one and ten.

## Constructive Health Work of the Academy of Medicine

THE Public Health Committee of the New York Academy of Medicine has now been functioning for twelve years and has acquired a definite and somewhat unique position of usefulness. Some of the specific things that it has done during these years are described in this issue of *THE NATION'S HEALTH* but the character of the work is such that it deserves a very special emphasis.

The Public Health Committee of the New York Academy, Dr. C. L. Dana, Chairman, is composed of a group of physicians who have had large experience in the practice of medicine, in hospital work, in teaching institutions, and in libraries. They are equipped, therefore, to look at problems of public health from a somewhat different point of view to that of those who are actively engaged in administrative or practical field work. Their interests incline them often to study problems not directly concerned with preventive medicine, such as legislative procedures, hospital and dispensary organization, medical education, nursing, social problems, and those city budgets which bear on hospital administration and public health. They have been able to conduct special

studies along some of these lines and to evaluate and standardize various types of hospital, dispensary, and public health work. None of the members of the Committee is connected officially with any of the branches of the city or state government, and this fact gives to their opinions value as those of an independent and unbiased body. In all important matters also, the Committee's opinions, with certain restrictions, are the opinions of the Academy of Medicine, and this fact gives greatly added weight. The plan of thus organizing and standardizing the experience and expert knowledge of a group of medical men in connection with the Academy of Medicine has appealed to people interested in public health and the Committee has received very generous financial support. They have been able to make large yearly budgets and to direct the expenditures of large sums in addition, in studying special problems.

Finally, the activities of the Committee are altogether impersonal: it is the Committee and the Academy of Medicine which are exploited not the individual. This fact makes it possible to give full publicity to the work without causing offense or arousing criticism.

There is no reason why similar methods of organization and work should not be adopted in connection especially with the large incorporated

medical organizations of the country. An essential thing in making these committees effective, however, is that they have sufficient money to pay for secretarial and executive work.

### The Cleveland Hospital and Health Survey; Two Years After

HOW rare it is to find a patient so considerate and interested in the impersonal aspects of his disorders as to take the pains to continue the physician's analysis and actually to record the changes produced by time and treatment so that others may receive benefit from the accumulated experience. But this is essentially what that thoughtful and alert community patient, the city of Cleveland, has done in handing us a neat postscript or supplement to the history, physical examination, diagnosis, prognosis and suggested self-treatment which were indulged in on the initiative and with the broad ideals of the Cleveland Hospital Council.

This is by no means an autopsy, nor yet the final estimate of disability on discharge, for the patient is still under treatment and in a fair way to make continued progress.

The Cleveland Welfare Federation accepted the suggestion of the survey of 1919 and made provision for the health elements in its community program by engaging a physician to be responsible for the preventive medical phases which form so important a part in most social, relief and educational measures supported by the voluntary taxation of the annual "drive." In this way the patient is assured a competent professionally trained observer and critic to supplement, so far as funds permit, the official and public services of the commissioner of health.

A great merit of this supplementary diagnosis is the frankness with which the patient calls attention to the errors of judgment and opinion and in some instances to misinterpretation of facts by the original surveyors.

Without engaging in the tempting game of concentrating a summary we can pick out some notable points which, by further reading in the original text, will develop value to any urban community.

In our opinion it (The Hospital and Health Survey) not only has paid for itself many times over in dollars and cents, but also in increased human values; and, as the years roll by and further steps are taken along the lines suggested, even greater results will be recorded in added days of life, work and happiness.

The Survey helped greatly to lift us out of the rut of things and show us the fair land.

And this from a patient who paid \$53,000 plus for a medical opinion. Really not a great extravagance when figured at seven cents apiece for the entire city family.

Here and there, as in the field of tuberculosis and venereal diseases, stagnation, or at least no progress, is recorded. Cleveland still has confidence in relief from its serious financial limitations and other insufficiencies and inadequacies of laws, through other interests than those dedicated solely to welfare and public health objectives, though the survey urged the necessity of enlisting public spirited lawyers and those in public office to take the initiative in a program for improvement of laws.

Some of the predictions or warnings have come true and we see Cleveland now at the moment of opening its new, generous City Hospital facilities for the indigent sick still at the mercy of partisan politics in the matter of its public hospital administration. With such brilliant examples of high grade hospital organization and the most liberal vision of the social function of hospitals for prevention and treatment as are found in Mount Sinai and Lakeside Hospitals at present, the inadequate direction of the city hospital stands out with especial clearness.

Lack of public funds and an entirely rational determination to maintain a proper sense of proportion among the projects of the many needy groups of the Welfare Federation has prevented completion of some of the desirable projects urged by the health survey.

Many improvements of the greatest importance have been accomplished by the health commissioner within the scope of his office, but he still lacks funds for health education and without this he is, in large measure, tongue-tied. In control of communicable diseases and in vital statistics radical gains have been made in organization and service.

Also in the division of medical inspection of the Board of Education advances in thoroughness of technic, in extent of service and in attention to ventilation and sanitation of schools show a fine record.

Among the volunteer health agencies the most remarkable record is presented by the Association for the Crippled and Disabled. Centralization of direction has been emphasized and a program of great completeness has been carried out.

In the field of education in medicine and associated professions, the nurses and pharmacists have carried off the palm for increase in facilities for theoretical and practical training under university auspices. Perhaps in the not too distant future even medical students may have as good facilities for the study of health in the process of destruction, and disease in the making, as are now offered to nurses through supervised field experience in homes.

The medical profession, the hospitals and their stepchildren, the dispensaries, are shown in the process of readjustment to their new obligations to society. Their reaction to the Survey study had been quick, effective, and liberal, and it is not too much to say that the dispensary committees of the Cleveland Academy of Medicine and of the Cleveland Hospital Council have taken positions and assumed leadership in medical service policies which deserve the highest praise from their colleagues and the community as a whole.

The lesson to be learned from "Two Years After" is definite and compelling—that a diagnosis and a plan of action are desirable, present true economy, and insure definite progress when dealing with a community as with an individual patient.

We congratulate Cleveland on its follow-up as upon the initiative of its Hospital Council in the original project and publication.

---

## Health Insurance Versus Health Centers

A RECENT book by Gerald Morgan<sup>1</sup> entitled "Public Relief of Sickness" should be read by all who are interested in the complex problem with which it deals. The author reviews the conclusions of the Illinois Health Insurance Commission which show very clearly that there is a considerable group of families with meager incomes who suffer severely for lack of medical treatment and for lack of a financial reserve sufficient to tide over periods of disability; and which show with equal clearness that none of the present methods of voluntary insurance in force in the United States is competent to meet this need. The results of state-aided voluntary insurance in Denmark and of compulsory state insurance in Germany and England are discussed in detail and with unusual balance and discretion. The Danish system is ineffective from the standpoint of cash benefits and both the German and English systems, while more successful in relieving the financial burden, are wholly inadequate from the standpoint of medical relief except perhaps in a few local instances such as that offered by the city of Leipzig. The author then proceeds to the fundamental thesis of the book, which is that financial relief and medical relief should be divorced and treated on a separate and independent basis. Where the attempt is made to furnish medical relief through an insurance scheme the contributors have proved unwilling to meet the cost, which necessarily advances by leaps and bounds with the

progress of medical science, and "insurance medical practice obliged doctors to make strict contracts, or bargains, for their services, to a certain part of the community, thus emphasizing the commercial side of medical practice to its professional detriment, which in turn, reacted upon the adequacy of the treatment actually accorded to patients."

The author then proceeds to analyze the sickness insurance plan presented by the New York senate in 1919 but defeated in the assembly and concludes that if the element of medical relief were eliminated a scheme of this type should prove adequate and satisfactory for an equitable distribution of the financial burden of sickness. He makes the admirable suggestion that the proportion of the cost of such a sickness insurance scheme to be borne by the employee should be fixed, while that borne by the employer should be flexible according to the actual incidence of sickness in a given industry—a plan which would prove a powerful stimulant to the development of industrial hygiene.

For the solution of the problem of medical relief the most promising plan yet proposed appears to be the health center bill, introduced in the New York Legislature in 1920 and 1921, which separates medical relief entirely from cash insurance and works on the principle that adequate medical treatment should be provided not merely to the wage earning class, while actually in employment, but at all times and to the entire public. The essential elements embodied in the New York Health Center Act were the provisions of adequate medical treatment at all times to all in need of it irrespective of their means, involving whatever extension of hospital and dispensary facilities would be necessary and the staffing of such hospitals and dispensaries by paid physicians. This end was to be attained on the voluntary initiative of local authorities but stimulated by state aid. Laboratory service and public health nursing service are also included in the plan but home visits by physicians such as is included in the work of the dispensaries at Zurich, Switzerland, is not provided for.

The whole question of so reorganizing the medical profession as to meet community needs is so complex that its solution must no doubt be sought along many different lines and to meet many local conditions. That such constructive action is essential will probably be granted by all dispassionate students of the subject, particularly for the sake of meeting the urgent needs of the rural districts. Whatever steps are taken, however, must be, on the one hand, such as to insure that public support which will provide the necessary

<sup>1</sup> Morgan, Gerald: *Public Relief of Sickness*. The Macmillan Company, New York, 1922.

funds, and in the second place to safeguard the standards of medical practice. It seems probable that both these ends are more likely to be obtained through the expansion of the health center idea than by a plan of health insurance which includes medical relief, and Mr. Morgan's book should prove an important factor in clarifying the thought of the medical profession and the public in regard to this vital question.

## Potential Economies in Plumbing and Ventilation Practice

IT IS wise to take every precaution which is of demonstrable and substantial value for the protection of the public health, and every year new lines of possible activity develop which promise a return in life and health far in excess of their financial cost. On the other hand there are many sanitary practices now current which rest upon pre-scientific prejudices rather than exact knowledge, and as our science progresses it is the duty of the public health worker to see that economies should be made wherever such practises are shown to be unjustified. Two substantial advances along this line are chronicled in the present issue of THE NATION'S HEALTH.

The report which has been circulated in tentative form by the sub-committee on plumbing of the Department of Commerce building code committee crystallizes the well established opinion that most of the municipal plumbing regulations now in force are quite unnecessarily severe and impose an unwarranted burden upon every one who builds a home. The substitution of vents for groups of plumbing fixtures instead of vents for individual traps is clearly indicated by all recent studies of this problem, and the recognition of this fact in our plumbing codes should prove a substantial stimulus to the building of small homes, so much needed in most large cities.

Of equal importance are the findings of the New York State Commission on Ventilation in regard to the possibility of ventilating school buildings by the use of window inlets with gravity exhaust ducts involving a substantial reduction in the volume of air supply with consequent decrease in heating costs as well as markedly lower costs for first construction. The system of gravity ventilation was used with marked success during the nineteenth century by Tredgold and Reid in England and by Billings in this country, but between 1890 and 1910 there was a rapid substitution of fan ventilation, stimulated by the belief that large volumes of air were essential for the

dilution of hypothetical toxic substances in the expired air. By 1917 twelve states<sup>1</sup> had laws or state regulations requiring the supply of about 30 cubic feet of air per minute per pupil in school-rooms, while two other states<sup>2</sup> had regulations which were only slightly less severe. The New York studies show that an exaggerated air flow is not only needless but positively harmful, since it involves a corresponding increase in air temperature, and it is hoped that vigorous steps will be taken to secure the modification of these misguided laws.

It is impossible to make any exact estimate of the money which can be saved to the house owner and the tax payer by the application of the principles laid down in these two reports; but taking the country over it must certainly run up into millions of dollars per annum.

## Gaps in Our Knowledge of Epidemic Poliomyelitis

THE conclusions of Wickman,<sup>1</sup> Kling, Peterson and Wernstedt<sup>2</sup>, Flexner<sup>3</sup>, and Emerson<sup>4</sup>, that epidemic poliomyelitis is primarily a contact-borne disease spread by the discharges from the nose and throat, has received fairly general acceptance in this country since 1916. The occurrence of sporadic cases without known contact and the failure of the control measures applied in 1916 have been explained on the assumption that well carriers play a predominant part in the dissemination of infection.

In view of the increase in poliomyelitis reported this fall from certain localities it is interesting to observe that at least one student of this disease, William Browning, has recently challenged some of our most cherished preconceptions in regard to it. Dr. Browning<sup>5</sup> maintains that the clearly demonstrated presence of the virus of poliomyelitis in the upper respiratory tract is no proof that this is their normal point of egress and ingress. He cites, on the other hand three facts, (a) the sporadic occurrence of the disease, with rare evidence of direct contact, (b) the seasonal prevalence of the disease, and (c) the prodromal gastro-intestinal symptoms, as evidence in favor of the alimentary tract as the primary portal of infection. The sporadic occurrence may be explained, as noted, by widespread vital resistance and a large number of carrier cases. We confess, however, that the fact that poliomyelitis

<sup>1</sup>Indiana, Louisiana, Maine, Massachusetts, Minnesota, Montana, New Jersey, New York, North Dakota, Pennsylvania, Utah, Virginia.

<sup>2</sup>Illinois and Ohio, requiring six changes of air per hour.

is so predominantly a disease of warm weather and of dry seasons as shown by Hull<sup>6</sup> has always appeared profoundly puzzling. It seems to offer convincing evidence that some factor is at work in this case which does not operate in any of the contact-borne respiratory diseases. The stubborn exception which fails to fit in with our theories is likely to be most fruitful in the advance of knowledge. If we knew why poliomyelitis occurs chiefly in the summer time the possibilities of control might be substantially improved. Meanwhile with our present ignorance we shall do well to accept Dr. Browning's "shot-gun" advice to parents.

(1) Do not have the child travel, or not beyond the ordinary rounds. Home life favors the preventive program. (2) Have the child avoid all food and drink except at home. (3) Give only freshly cooked food—even milk and water to be sterilized. (4) Avoid all raw fruit. (5) Do not let the child fondle pets. (6) Protect both the child and its food from all insects and vermin. (7) Keep the child from kissing, fondling, and hand-shaking. (8) Prevent all bathing and swimming in polluted water. (9) Observe general cleanliness and care of the laundry, with avoidance of public drinking cups and like utensils. (10) In case of the least digestive disturbance have it attended to immediately. The writer admits that some of these rules may not be necessary but they involve no serious hardship and are intended to cover all possible sources of infection.

### Some Anatomical Factors in the Etiology of Tuberculosis

THE terms "resistance" and "susceptibility" serve in too many instances as convenient cloaks for profound ignorance. A multiplicity of factors, chemical, physical and anatomical, local and systemic, play a part in the skirmishes which terminate either in a lodgement of invading bacteria within the tissues or in their failure to so establish themselves. It is peculiarly refreshing to find evidence of the actual nature of some of these factors and of their relative importance in a given case.

A suggestive contribution to this problem in the case of tuberculosis comes from Dr. A. K. Krause's laboratory<sup>1</sup>. The studies in question were initiated by the observation that in guinea pigs inoculated in the groin with tubercle bacilli of low virulence there were two centers that bore the brunt of the infection; the inguinal and retroperitoneal lymph nodes and the tracheobronchial nodes. It was not easy to explain why the infection jumped to the tracheobronchials without leaving its marks between. Subsequent studies showed that from four to twenty-six days after infection in the groin, guinea pigs had received and retained more bacilli in the tracheobronchial lymph nodes than in the lungs. Following involvement of the lymph nodes tubercles appeared

first in the spleen, which became highly tuberculous before the lungs showed any infection. In view of the fact that there is not, as some authors have assumed, any direct lymphatic connection from retroperitoneal lymph nodes to either spleen or tracheobronchial nodes, it must be assumed, until positive evidence to the contrary is brought forward, that the course of the bacilli was through the dorsal lymphatic trunk to veins, at the junction of internal and external jugulars, and thence through right heart and pulmonary artery to the lungs where some bacilli are embolized in capillaries of venules, thence out of the smaller blood vessels and into the lymphatic system of the lung and back to the tracheobronchial nodes.

The distribution of infection in rabbits was found to be almost an exact reversal of that found in guinea pigs. In the former there was marked involvement of the lungs with little or no gross change in the spleen, and even though pulmonary tuberculosis was extreme there was slight or moderate infection of the tracheobronchial nodes.

The bronchial artery, which in the guinea pig supplies all lymphoid tissue within the lung, arises not, as in other mammals, from the dorsal aorta or the intercostal, but from the right subclavian artery, while in the rabbit it is the pulmonary and not the bronchial artery that carries blood to this tissue. These facts, worked out by Miller<sup>2</sup>, and Willis<sup>3</sup>, respectively, show the need of more detailed study of the animals used in laboratories for experimental purposes. In this case it gives at once a reason why an infection brought to the lungs from the periphery, by way of lymphatic system and veins, should eventuate differently in rabbits than in guinea pigs.

Anatomical studies of the lung tissues corroborated facts that have previously been recorded but had received little attention; that throughout the lungs of rabbits there are innumerable masses of lymphoid tissue; and that this condition is not found in any appreciable degree in the guinea pig.

In the rabbit these masses of intrapulmonary lymphatic tissue tend to interrupt the passage of bacteria from the lung to the lung nodes and to confine infection to the lung itself. In the guinea pig with a more "open" lung little obstruction is offered to the passage of bacilli till they reach the tracheobronchial nodes. An additional factor favoring pulmonary infection in the rabbit is that the pulmonary artery supplies the lymphoid masses in the lungs, thus carrying directly to

them the bacteria that have converged from the periphery of the body to the venous trunks.

The significance of this whole study is shown by the questions raised by Dr. Krause. "Does human tuberculosis infection normally tend to the lung root in early life because then lymphatic drainage is more active and intrapulmonary channels more open and unobstructed than later. In other words, is the child's lung more comparable to that of the guinea pig, which may be looked upon as constituting one type?"

"With increasing age, do human lungs undergo internal changes which bring them nearer to the type which is normal for rabbits? Does there normally occur an increase and development of intrapulmonary lymphoid tissue, over a few years or through many years? Do formerly open lymphatic paths thus become more or less obstructed, so that bacillary retention within the lung is favored? How much do the inhalation of foreign bodies and the repeated occurrence of respiratory infections alter puerile lymphatic structure which was once normal?"

## The Drift of Population From Rural to Urban Communities

DEMOGRAPHERS found, as the results of the last census became available, that the condition they had anticipated had become a reality. More than half of the population of the United States now resides in urban communities, which the Bureau of the Census defines as cities or incorporated places having a population of 2,500 or more.

The District of Columbia, being coextensive with the city of Washington, naturally leads the list of major divisions with an urban percentage of 100. Rhode Island is credited with 97.5, while Massachusetts (94.8), New York (82.7) and New Jersey (78.4) all show percentages over 75. At the other end of the scale are nine states with an urban population including less than 25 per cent of the total number of inhabitants for the state. The lowest percentage, 13.4, is credited to Mississippi.

During the last two decades Arizona and Idaho have doubled, Oklahoma has tripled, and Idaho has quadrupled the percentage of urban population. Colorado, Montana, and Wyoming have experienced a diminution of urban population percentage during the last decade and the two first mentioned show a smaller per cent of urban population in 1920 than they did in 1900.

The urban population percentage of the United

States as a whole has grown steadily. In 1890 it was 35.4 per cent; in 1900, 40.0 per cent; in 1910, 45.8; and in 1920, 51.4 per cent.<sup>1</sup>

The rural communities have lost their majority. The "back to the farm" movement seem to have had no appreciable influence on the trend toward urbanization. From the time of Malthus up to the present day, philosophers and scientists have studied the problem of the future food supply of the world. From a mathematical point of view it is not difficult to conceive of a time when, if the present movement to the cities continues, the increased production from scientific farming will not be sufficient to outweigh the loss in the ranks of the agriculturists. It is not assumed that the force of urbanization affects solely the group following agricultural pursuits but it cannot be without its effect. A closely related fact, significant in this connection, is that before the census of 1910 there had been a steady decline<sup>2</sup> in the percentage of those gainfully employed in "agricultural pursuits." With the census of 1910 the new classification of "agriculture, forestry, and animal husbandry" was introduced. The last census permits a comparison on this basis which shows that not only has there been a reduction in the per cent of the total population so employed (approximately 3.5 less in 1920 than in 1910) but also that the actual number so employed has been reduced by nearly one and three-quarter millions.

The problem is so complex that few dare to state the cause or the probable finale. To the men that the political spell-binder calls the backbone of the nation, "toil's bright dew-drop" seems to have lost its charm.

## Psychologic Factors Determine Success in Group Feeding

ACCESSORY food factors is a phrase which has come to have a definite chemical significance in nutrition studies. There are other "accessory food factors," not of a chemical nature, which, especially in problems of group feeding, are equally important. These other food factors, even less tangible and less definite but no less fascinating or interesting than the chemical ones, are mainly psychological, racial, and environmental factors which must be understood before successful group feeding is possible.

Any attempt at teaching the elements of nutrition to a group will fail unless the teacher starts where the group leaves off; that is; the teacher must understand the standards of the group before such standards can be changed. Hopeless chaos results from attempting group instruction

1. Statistical Abstract of the United States, 1921.  
2. Thirteenth Census of the United States, v.iv.

of mothers and housewives of different nationalities and different environment; the Jewish housewife can not be shifted from a "Kosher" basis. The Italians will have difficulty in changing from their accustomed liberality of farinaceous foods. If corrections are necessary, they cannot be put over from a textbook; and they can only have meaning when based on the idiosyncrasies of the individual groups. For the study of these peculiarities, training is necessary in much more than the science of nutrition. In historical perspective and appreciation of the development of habits of cooking and eating, knowledge of economic possibilities and limitations, understanding of environmental influences, and, finally, a psychological insight into the particular present-day family life of the group under study, must be considered part of the necessary equipment for study. Pernicious dietary habits may usually be traced to individual and collective mental set rather than to wilful perversion, and the remedy lies in a full understanding of the patient.

These ideas received their stimulus from perusal of an unpublished report of some recent nutritional studies in Chicago. A fund was available for the purpose of supplementing the income of families containing undernourished children. The work was carefully done under the supervision of trained case workers, medical agencies, and dietitians, and after two years an inventory of the experiment was recorded. In this particular study only one large immigrant group was included, so that many of the larger factors mentioned did not come up for consideration. Yet the surprising and striking feature of the whole study was the tremendous effect of psychological factors on the simple physiology of nutrition. A given family received money enough to allow all its undernourished members to gain. The children did not gain. The next family under apparently identical conditions, showed better than an average. Such marked differences were difficult to interpret. Closer analysis disclosed in the first instance a father with an "inferiority complex" standing unconsciously in the way of his children's better health. The second family were of better stock, perhaps temporarily down; the father and mother were intelligent and receptive. Each family under observation proved that there's many an unseen, unchartered obstacle between the food and the feeder, and emphasized the deductions we have drawn. We are of the opinion that just as the psychological stimulation of digestive juices plays an important rôle in the nutrition of the individual, so psychological—and other elements—are highly important factors in the nutrition of groups.

## The Medical Certificate of Death

EACH year the director of the United States Bureau of the Census introduces into his report an admission that the country as a whole has very incomplete records. While the Registration Area now accounts for 81.1 per cent of the population, there are still fourteen states with such incomplete death registration that the Federal statisticians do not consider their certificates worthy of recording.

The unreliability of statistics of causes of death as concerning all classes of citizens is fully discussed in a recent issue of the *Journal* of the American Medical Association by Erik G. Hakansson, Lieutenant, of the U. S. Navy Medical Corps, who argues that the confusion resulting from the use of physicians of vague and incomplete statements placed 15,505 deaths under "ill defined" diseases in 1920. He reports fully on a system of death registration giving one hundred per cent satisfactory medical certificates as being in use in St. Thomas, Virgin Islands, and which he considers to be perfectly applicable to the United States as a whole.

The cooperation of the medical profession is the first essential in achieving reliable statistics. If the facts are not discoverable from official records, what precision can attach to preventive methods? Ambiguity of terms and clear thinking are incompatible, and the medical certificate should command its share of attention, for emphasis in health work find its guide in statistical interpretation.

## Beginning Soon Enough

D R. CHARLES J. HASTINGS told a story at the A. P. H. A. meeting in Cleveland which illustrates the spirit in which he has built up the Toronto Health Department to a point perhaps unexcelled upon this continent. The gate-man at a railroad station is commiserating with a would-be passenger who returns, puffing and panting, from the unsuccessful pursuit of a departing train. "You didn't run quite fast enough," he says. "Yes I ran fast enough" is the reply, "but I didn't start soon enough."

The control of infant mortality demands the care of the expectant mother. The control of diphtheria depends upon immunization before the school-age. The mental hygienists tell us that the most important steps in the architecture of the mind are taken before the age of six. The *pre-tuberculous*, the *pre-school* period, *pre-natal* work—these are the keynotes of the modern public health campaign. To start soon enough is the secret of prevention.

## National Program of Vocational Rehabilitation

BY JOHN A. KRATZ, CHIEF, VOCATIONAL REHABILITATION DIVISION, FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.

THE Federal Act for the promotion of vocational rehabilitation of persons disabled in industry or otherwise became effective June 2, 1920, and prior to this time some of the states had enacted rehabilitation legislation, but only five or six of them had actually begun the work. In order to receive the benefits of the Federal Act, the State must accept its provisions by an act of the legislature. Thirty-four states are now cooperating with the Federal Board of Vocational Education, the agency which administers the Act, and assurances have been received indicating that in all probability legislatures in 1923 will make the number forty-two.

Despite the post war depression, and consequent economic programs inaugurated in the states, there has been a very gratifying extension of the rehabilitation service throughout the country. During the fiscal year 1920-21, 457 persons were completely rehabilitated. At the close of that year 1,013 persons were receiving some form of rehabilitation service. During the fiscal year 1921-22, 1,900 persons were completely rehabilitated. At the close of the same year more than 8,000 persons were receiving some form of rehabilitation service. By November 1, 1922, the roll of active cases had reached ten thousand. That these figures are significant will appear from statements made later in this article. The vocational rehabilitation and return to employment of disabled workers under state auspices is comparatively a very new project. Much has yet to

be learned as to the most effective means of refitting the disabled for remunerative employment. As the states develop the mechanics of case procedure and increase the number of their cooperative contacts with other agencies, the number of reha-

A disabled worker who through the Rehabilitation Department of his state was enabled to carry on successfully and secure promotion in cotton mill work.

bilitations will increase correspondingly. The prospects for future development of the work, and increase in volume of service are, however, bright, although dependent upon many factors.

The Federal Act promotes the vocational rehabilitation of disabled persons and their return to remunerative employment by providing for Federal and state cooperation. The state is directly responsible for the work, receiving from the Government annual allotments of money, its allotments being in the proportion of its population to the population of the nation. Expenditures from the allotments of Federal money must be matched by expenditures from state or local funds, public or private, used under public supervision for purposes which are permitted under the Federal act. The Federal Board of Vocational Education is the Federal agency cooperating in administration of the act, making the allotments, and promoting standards. In the state, administration of the rehabilitation service is in the hands of the State Board for Vocational Education, which, under the act, must cooperate with the agency that administers the state workmen's compensation law. In several states, the state board has delegated the direct execution of the work to the labor or compensation department, but, of course, has not relinquished its responsibility for administration and supervision within the state.

The act does not specify how rehabilitation is to be effected, but the Federal Board recognizes the following avenues to vocational rehabilitation and return to employment:

(1) Service leading to physical reconstruction resulting in suitable employment; (2) service providing artificial appliances as vocational aids

A corn shredder victim, now the only one-armed blacksmith in his state.

and leading to suitable employment; (3) service providing suitable work, or work conditions, for persons with disease tendencies; (4) service providing opportunity for the person to become established in a business of his own; (5) service providing suitable placement in employment; (6) service providing training resulting in suitable employment. Federal funds may not be used for physical reconstruction, for living maintenance, for purchase of office equipment, or for buildings or land. Living maintenance is provided through such sources as accident compensation, the person's resources, loans, contributions from private sources, or state funds provided specifically for the purpose. The states which now have maintenance funds are Minnesota, Massachusetts, New York, New Jersey, North Carolina, Pennsylvania, Wisconsin, and Wyoming. These funds are provided through general state appropriations or as additional compensation.

### Cooperating Agencies

Because of variations in age, disability, education, experience, capacity, and spirit, disabled persons must be dealt with individually, not in groups. Each case presents its special problems. Frequently it is necessary for the rehabilitation department to appeal to other state departments, or to private agencies for special services. A recent case will illustrate. A young man with a left leg amputation a little below the knee came to the attention of the rehabil-

itation service in one of the states, and it was seen that the most feasible program of rehabilitation would involve the provision of an artificial leg. Accordingly he was taken for a fitting, but it was discovered that the stump has been sloughing, and was, therefore, in no condition to take an artificial appliance. The doctor who was consulted advised that an operation would be necessary to put the stump in condition. Inasmuch as the rehabilitation department could not pay for surgical operations, it was necessary that the services of some other agency be enlisted. Through the efforts of interested persons who were cooperating in the case a social agency contributed funds not only for the operation, but, also, for hospital expenses. After these preliminary measures, the young man was inducted into training, and finally readjusted to remunerative employment.

It would be impracticable to illustrate the many kinds of services which are needed from others. Among the most important or necessary at times is that of living maintenance. For this assistance, the rehabilitation department must go to outside agencies when compensation or state funds are not available. Frequently provisions must be made for the family of the disabled person while he is being retrained. The following are some of the services which are provided by cooperating agencies:—Reporting cases, financial aid, advisory service, making survey, therapeutic aid, reinstatement in union, giving employment, encouraging disabled person, family rehabilitation, influ-

encing public opinion and sentiment for the work, influencing persons to accept the rehabilitation service, providing artificial appliances or teaching equipment, setting up disabled person in business, and vocational advisement. Some of the agencies which cooperate are:—State medical associations, county medical societies, hospitals, councils for social agencies, associated charities, district nurses, Red Cross, Rotary, Kiwanis and Lions clubs, newspaper associations, societies for crippled children, parent-teacher associations, Y. M. C. A., Y. W. C. A., Chambers of Commerce, state and county officials, church associations, fraternal orders, Federations of Women's Clubs, labor organizations, employers, and employers' organizations, and individuals.

### Organized Cooperation

It has been shown that in many cases special services must be secured from other agencies which are better prepared than the rehabilitation department to render them. Despite the great variety of assistance which the department finds available, because of its limited staff, and in many states large territory to be covered, the rehabilitation service is forced to seek the cooperation of local communities. This is best effected when the community is made to realize its responsibility for its own handicapped. Usually it is not difficult to influence the community to realize this responsibility.

In the program of rehabilitation of a single individual there are frequently multitudinous details. Often

A worker who lost both hands from electrical burns. His company supplied the artificial arms, and through the cooperation of the rehabilitation officials gave him an important outdoor position.

the person needing the service must be sought out, must be visited at the hospital to prevent loss of morale; he must be interviewed often a number of times for the purpose of taking a mental, and spiritual status. On the basis of this so-called survey, at least a tentative plan of rehabilitation must be developed, frequently necessitating conferences with prospective teacher, employer, and other persons involved. Generally speaking, first eligibility and, later, susceptibility must be determined. From the inception to the close of the case many services must be rendered, a large proportion of which might be performed by agencies or individuals in the community of which the disabled person is a resident.

A number of the states have developed a system of organized cooperation to meet the above situation. Clearing agencies to whom cases are referred for preliminary study and recommendations are established in communities. The function of such clearing agencies is to save the rehabilitation department much work which it would otherwise have to do. This agency may give assistance in the determination of eligibility, susceptibility, or in the preparation of tentative plans of rehabilitation. Usually the clearing agency consists of a representative of the state department of public health, or public welfare, or of a social agency, or other interested agency or individual. This agency is instructed relative to the benefits of the act and the kind of service the state can render. The work of the agency is done in close cooperation with, and under the direction of the state department of rehabilitation. All cases originating in the territory for which the agency is responsible are referred to it. After a careful study of the case, a representative of the clearing agency interviews the disabled person. His findings and suggestions are forwarded by the clearing agency to the state department.

As far as possible, the work of these agencies is supplemented or supported by advisory committees, usually consisting of four, five, or six members. A typical committee might consist of representatives from each of the following organizations: Vocational Education Department, Red Cross, Employers' Association, Bureau of Community Welfare, District Nurses, Employment Office, County Agricultural Agent, Employees' Association, etc.

The function of the advisory committee is to discuss the cases which

At the age of thirty-five this man lost his left foot. He is now operating his own grocery store. Compensation funds paid for the original stock. The Rehabilitation Service provided a special course in elementary accounting.

have been referred to it by the clearing agency or state department, and as far as possible to endeavor to develop in each case a plan of rehabilitation. Not only do the committees make recommendations as to possible programs, but they go further in some instances and assume the responsibility for seeing that employment is guaranteed at the conclusion of the training program. In addition, these committees often plan for the provision of maintenance or physical rehabilitation, or such other activity for which the Federal or state funds may not be used. In short, the main function of the advisory committee is to assume in large part responsibility for the rehabilitation of persons whose cases come before them for consideration, thereby relieving the state department of many activities which the local committee might often be better qualified to perform. It should be understood, however, that the advisory committee has no power to act where the expenditure of Federal or state funds is involved. In fact, the committees' recommendations are referred to the state rehabilitation service, which must pass upon them before they can be effective. From

time to time state officials meet with advisory committees.

It is evident that under such a plan the state rehabilitation service is saved considerable expenditure of time and money. The advantages of such a plan to the state rehabilitation services are evident. One of the outstanding of these advantages is that the responsibility for the rehabilitation of disabled persons in a community is placed upon that community. It has been found that most communities are ready and willing to assume the responsibility, and wherever cooperating committees have been organized, they have been for the greater part rendering conscientious and effective service.

The success of the plan depends very largely upon the administrative ability of those who have charge of the state rehabilitation service. They must be organizers, as well as executives, and must possess tact and diplomacy. There is danger that the work, when tied up closely with social agencies of a definitely charitable nature, will be looked upon as charity, not only in the minds of the recipients, but also in the minds of business, professional, social, and industrial management people who co-

His left hand practically useless, this young man was discovered to have a talent for drawing. Once a farm hand, now a sign painter

operate in local communities. Inasmuch as social workers feel an equal responsibility for bedridden cases, paralytics, children, and the chronically sick, these naturally are brought to the attention of the service, although in many cases they are ineligible for, or not susceptible of vocational rehabilitation.

For the most part, the state rehabilitation laws, being acceptances of Federal legislation, are uniform as to benefits. These consist mainly of tuition for training, provision of instructional supplies, and under certain conditions, instructional equipment for individuals, prosthetic appliances when aids to vocational rehabilitation, and all services in connection with advisement, placement, and follow-up to a logical conclusion in remunerative employment. Some of the states can do more. For instance, in New Jersey physical rehabilitation clinics are maintained in five centers, for the purpose of providing physical reconstruction or therapeutic treatment. In many cases the only avenue, or it may be the best avenue through which vocational rehabilitation should be attempted is physical reconstruction. In states whose rehabilitation laws do not permit expenditures of their funds for physical reconstruc-

tion, other methods of securing it, when needed, must be resorted to.

tion, other methods of securing it, when needed, must be resorted to.

In Iowa there is a hospital law which provides disabled persons with everything needed in the way of medical and surgical treatment.

Often in other states state-aided hospitals are used, while at times this service is secured through charitable assistance of both individuals and organizations, as well as the medical fraternity in general. Reference has been made above to those states whose laws provide living maintenance for disabled persons while in re-

The nation at large is convinced of its obligation to fit or re-fit handicapped persons for remunerative employment. The work is new, and consequently for the next few years new methods of procedure and administration will be discovered and tried out. Some research is now being made in some of the states looking to the discovery of the kinds of employment in which physically disabled persons can carry on and to advantage. It is being demonstrated that to be disabled does not mean to be unable. Since June, 1920, the activities of the Federal Board have been almost wholly needed and given to assisting the states in setting up their rehabilitation machinery. Five bulletins have been prepared upon various phases of the work, which set forth policies of administration, methods of procedure, and material for the general promotion of the work. In the next few months, there will be published a bulletin which was prepared by the National Tuberculosis Association, in cooperation with the Federal Board, entitled "Problems of the Tuberculosis in Employment." Plans are now being made for research in several fields, looking to advancement of the program. The work in all of the states is still in experimental stages.

## Dental Service in Industry

THE close relationship between certain industrial diseases, notably lead poisoning, and diseased teeth was one of the moving causes for the survey made during 1921 by the division of hygiene and engineering of the Pennsylvania department of labor and industry to determine the extent of dental service for employees in industrial plants in the United States and Canada.

Replies were received from fifty-nine industries, ranging from 12 in Pennsylvania, 11 in Ohio, 8 in New York, 6 in Massachusetts, 4 in Illinois, 2 each in Michigan, Minnesota, New Hampshire, and one each in Alabama, California, Colorado, Connecticut, Delaware, Louisiana, Maine, Missouri, Rhode Island, Virginia, Wisconsin, and Ontario, Canada.

Thirty-three plants employing 209,743 reported that total number of employees taking advantage of dental service were 125,222 or 59.7 per cent. Fifty-nine plants employed dentists, 40 for full time.

From the replies of fifty-nine firms as to the number of assistants

in the dispensaries, it was found that 75 nurses, 26 attendants, and 26 clerks were employed in all the plants for dental service.

The average cost of original dispensary equipment to the fifty-three firms replying to this question was \$1,958.03; the least cost of equipment in one plant was \$328.28; the greatest cost was \$8,000; while the total cost in all plants was \$103,775.46. Cost of operating the dispensary per year per patient was,—average cost \$3.38, least cost \$0.30, greatest cost \$27.19.

Treatment given in the dispensaries circularized consisted of examination in 100 per cent of the plants; cleaning of the teeth in 96.4 per cent; radiographic work in 44.6 per cent; emergency treatment in 89.3 per cent; and examination, cleaning, radiographic, emergency, and operative work not emergency work in 30.4 per cent of the plants.

Fifty-five of the 56 firms replying stated that they considered the operation of an industrial dental dispensary a success; one considered it only partially successful.

# Industrial Medicine and General Practice

## Complementary Services, Not Professional Rivalries, Must Characterize Medical Organization

By C. C. BURLINGAME, M.D., SOUTH MANCHESTER, CONN.

THE men who are the oldest in the industrial medical field are more than ever before of the opinion that the position of the industrial physicians in the scheme of society is still undetermined. Even less definite is the matter of his future status. About the only thing they know for certain is that the industrial physician has seen fluctuations enough during the past few years to make him unwilling to predict what the future holds for him. Only a few months ago, we were prone to assert very glibly that industrial medicine as a new specialty had opened up great possibilities for the medical profession, but faith in industrial medicine as a great specialty with a bright future, has been severely shaken during the late period of industrial depression. Fired with the possibilities of medicine in industry, physicians entered industry as salaried men, submerged their individuality, and became an integral part of business organization. Then financial depression ensued and men of excellent type found themselves relieved of their duties, and given a choice of looking for other jobs or embarking anew as independent practitioners. While this dealt a severe blow to the class of so-called full-time industrial physicians, the fact that we have, in some instances, failed to develop adequate working relationships between medicine and industry should not destroy our faith in the future of this newer specialty.

Instead of referring to the "industrial physician," the whole subject may more properly be discussed under the inclusive term "industrial medicine." Whatever may be the problems of the industrial physician, industrial medicine finds a necessary division of function into (1) caring for medical and surgical conditions imposed upon the industry by legislation; (2) assisting in the physical placement of employees; (3) assisting the operation of benefit associations of various kinds; and (4) the maintenance of industrial efficiency through health measures. The caring for compensation cases, placement of employees on the job, and benefit association features, as medical prob-

lems are quite exclusively industrial and constitute a service that is largely a direct charge upon industry. But to what extent are the development of physical efficiency and the solution of health problems industrial rather than community or personal problems?

Whether future developments will show that it is to the best interest of all concerned for industry to operate its own medical departments or to have its surgical and medical work done by private physicians or groups of physicians, in the light of our present day knowledge we cannot say. Nor can we at present pass upon the merits of the part-time practitioner as against the full-time industrial physician, or upon the industrially controlled clinic as compared with the center operated by some community interest with industry bearing its share of the expense. Whatever the future may show to be to the best interest of the profession and the community, the problem of developing efficiency by health measures cannot be carried to its maximum by the sole efforts of any physician or group of physicians in the direct or indirect employ of an industry. So long as the American working man retains his right to choose the physician he wishes, just that long will it be to the interest of the industrial physician to form a partnership—to make this medical problem a common problem with the community practitioner and to enlist the support of every practising physician in the community in his efforts to help solve it.

### Many Problems in Common

Physical examinations for employment, caring for compensation cases, and the insurance features are simple in comparison with the problems involved in maintaining in general health and efficiency the industrial group, and it is in this most difficult part of the industrial physician's work that it becomes particularly important to enlist the cooperation of the general practitioner.

Some people believe that all men are competitors, and this being true, peace and harmony in society are de-

pendent upon the maintaining of competition only upon a fair basis. We must remember that the physician is *per se* an individualist and in the final analysis cannot be expected to welcome any scheme which will tend to lower his prestige or to cause his opportunity for personal service to the community to pass into the hands of someone else. Naturally, he cannot be expected to welcome any scheme which favors a selected group of men either in the employ of a company or subsidized by a wealthy concern with a prestige beyond the possibilities of the man in general practice, unless at the same time he is likewise afforded a fair opportunity to develop and gain prestige in his community.

It might be pertinent to discuss in this connection the question of what a financial advantage industrial medicine as a specialty might become to the general practitioner, but I believe the majority of physicians, even in this commercial age, would willingly make financial sacrifice if it were shown to contribute to the best interests of the community. On the one hand it looks very much as if the man in general practice would have to accept the industrial physician as a specialist, but he naturally views with some degree of uneasiness the tendency of industrial medicine to encroach more and more upon the field of general practice. In not a few instances it has gone as far as the company furnishing a corps of physicians to care for employes' families in their homes when ill. He may even visualize a future when the entire care of the working man will be placed in the hands of physicians hired by the company who have become part of a physical efficiency machine, and he asks himself if, in the final analysis, this is to the best interest of the profession or the community. If such a condition could be expected to develop, it must be conceded that the general practitioner would have a sound basis for his feeling of uneasiness.

It is quite impossible to lay down a set of rules which might be adopted for the working out of satisfactory relations between the industrial physician and the general practitioner

in every community. The local problem is bound to be peculiar to the particular industry and to each community; but there are certain fundamentals which should be noted in the establishment of any industrial medical department or industrial medical clinic. In establishing an industrial medical department it should constantly be borne in mind that it is poor business to destroy the prestige and efficiency of the general practitioner inasmuch as he is one of the partners of the industrial physician in solving the problems of health and efficiency. Would it not be better for the man devoting himself entirely to industrial medicine to confine his efforts to meeting the legal and moral responsibilities placed upon the employer, and use the private practitioner as far as possible in the work of solving health and physical efficiency problems of the industrial group? To be a little more concrete, could we not assign to the industrial physician the duties of inspection of health hazards within the plant, the care of conditions arising out of or in the course of employment, inquiry into occupational research, the administration of first aid medical and surgical treatment, the handling of routine minor illnesses which would not ordinarily reach a doctor but the treatment of which would keep the employee on the job, and the maintenance of the industrial dispensary as a general clearing house to direct employees into the hands of local physicians and specialists? To this end could not the industrial physician add to his personnel in the capacity of consultant any physician who cares for the employees of his concern? If the industrial physician drew the line at this point, and the man in private practice accepted this as a fair division of labor, it could be summarized as follows:

The industrial physician would be on a sound basis so long as he confined himself to meeting the moral and legal obligations of the company he serves, by proper placement of employees on the job, the necessary administration of any insurance schemes, and any other measures necessary properly to supervise the health of the employees. All else should be referred to the doctors in the community.

Further, the industrial physician under such an arrangement would place any and all facilities of the industry at the disposal of the private practitioner whose honest endeavor it is to return an employee to industry as completely and as quickly cured as

possible. Though this might be regarded as passing over to the private practitioner some of the prerogatives which could be enjoyed exclusively by the industrial physician, the industrial physician could thereby get the private practitioner into effective cooperation with his work and would become relatively more efficient. If, by backing the private practitioner, the industrial physician could successfully keep a larger group of his employees under the best medical and surgical supervision, it would mean a greater gain for him than if he undertook to do all the work himself, even though he lost an opportunity to build up a massive organization of doctors and nurses under his own personal control.

The more I see of the medical department in industry the more I am convinced that the rôle of the industrial physician should become more and more that of a friend and consultant of the private practitioner who is trying his best to make the working people well and keep them well.

It is a perfectly impossible social scheme for industry ever to consider placing on its pay roll all the physicians who may be caring for its employees. Unless that can be done, the private practitioners are going to play a larger rôle than the industrial physician in physical efficiency and health in industry, and there should be no rivalry between the industrial physician and the man in private practice. If such rivalries have arisen in the past, it is because the industrial physician has failed to appreciate that a successful and competent physician in the community is the best possible partner in solving the health problem of industry.

There are, however, many things which militate against the success of really sound theories of such cooperation. Absolute frankness and the fullest confidence on the part of both the industrial physician and the general practitioner are prerequisite. The general practitioner may feel that he loses cases to the industrial physician; and the feelings of the latter may be even more hurt when a patient could have received free treatment at his hands prefers to go to a private practitioner. Such a situation is obviated, however, if from the first, the industrial physician and the general practitioner will accept the division of duties herein outlined and it becomes perfectly possible to arrive at a peaceful, harmonious working basis. To accomplish this the industrial physician must remem-

ber that the man in private practice is essential to the success of the community and any cases not falling within his assigned duties must be constantly referred to the general practitioner. In referring cases there must be no preference shown between men who are striving to do good work in the community. The industrial physician must observe the ethics of his profession more strictly than almost any other type of professional worker. In case of doubt he must always favor the man in private practice. He must remember that patients may come to him with all kinds of wierd tales about what the other physician said, etc., statements which most likely have never been made or are misquoted and misunderstood. He must remember that he may have at his disposal a district nursing force who, believing in their industrial physician, could easily take advantage of a situation and divert cases; he must guard against this and see to it that his nurses are ethical in their practice and loyal to the private practitioner whose cases they are seeing. The road is full of pitfalls for the industrial physician who fails to impress upon his nurses the importance of being loyal to the attending physician.

#### A Reciprocal Relation

On the other hand, the private practitioner must remember that the industrial physician has a specific responsibility toward both employees and employer, and he should be willing to cooperate with the industrial physician in putting his job over even though it may mean the occasional loss of a case. He must be willing to give the industrial physician credit for wanting to have the confidence of patients and employees, even though he does not collect an individual fee for his services. He must be willing to appreciate that the industrial physician's stock in trade is not materially different from that of the private practitioner, that when the industrial physician fails to hold a patient it hurts him just as much, if he is conscientious, as it would the private practitioner. The industrial physician, therefore, naturally resents any acts or comments on the part of the private practitioner which tend to lessen the employee's confidence in industrial medical work. And, what is of the utmost importance, the private practitioner must have sufficient confidence in the industrial physician to meet him halfway to discuss the difficulties which lead to misunderstandings and wide breaches of

friendship for the industrial man.

At this point a word of warning is in order. Unless the man in private practice and the profession as a whole take more interest in solving the medical problems in industry, the financial interests are going to be ob-

ligated to undertake the health supervision of their plants without the aid of medical societies or ethical groups. The private practitioner who is not willing to devote some of his time to a study of the industrial conditions in his community is unfair to his pa-

tients. To serve his patients he must know the etiology of the diseases which he may be called upon to treat, and must know industrial conditions in order to pass upon the etiology of the diseases he encounters in his routine practice.

## Pioneer Industrial Hospital Erects New Plant

### Nurses' Home Included in Building Plans of the Cambria Steel Company

By JOHN B. LOWMAN, M.D., CHIEF SURGEON, CAMBRIA STEEL COMPANY, JOHNSTOWN, PA.

WHAT has been pronounced by many who have inspected it as the finest industrial hospital plant in the country has been completed recently at Johnstown, Pa., by the Cambria Steel Company for its employees. The hospital was opened for service July, 1921, and has accommodations for eighty beds—four wards and nine private rooms. The building covers approximately 16,500 square feet. The central administrative bay is four stories high including basement, and the two wings three stories.

The original hospital, a pioneer of its type, was built in 1887 under the direction of Dr. Webster B. Lowman, surgeon of the Cambria Iron Company, and was a frame structure with twelve beds. This was the first hospital ever operated by an industrial corporation, and from it similar enterprises in other localities had their incentive. The great benefits derived from this hospital required the addition of many departments, until in 1919 the cost of maintenance emphasized the necessity for a more modern building adapted to the best

industrial surgical work of the day.

Cambria Steel Company through its president, Mr. A. A. Corey, Jr., and under the direction of the chief surgeon, Dr. John B. Lowman, decided to erect a new building which would be in the line with the best modern hospitals in the country. The hospital staff and the engineering department were authorized to study prevailing practices in the newest hospitals. Representatives therefore made complete inspections of such existing installations, and the result of their studies is embodied in the new building.

It was found desirable to separate the nurses' quarters from the hospital department, and accordingly a nurses' home in a special building was authorized as part of the construction. After the plans had been properly discussed and the general working layout agreed upon as the best obtainable, the work was handed to Mr. Benno Jansses, architect of Pittsburgh, with instructions to furnish designs for both a hospital and nurses' home. The contract was awarded to Mellon Stuart Company

of Pittsburgh who finished the building according to time and specifications.

The nurses' home is adapted for housing thirty nurses and is complete in every detail. The first floor is devoted to reception rooms, private and public sun porch, toilets, lavatories, laundry and sewing rooms. The second and third floors are given over to private rooms equipped with baths, toilets and lavatories, private and general; on the roof is an open-air garden.

The hospital is of fireproof construction throughout, the walls being of red brick, the frame and floors of reinforced steel, the partitions of gypsum, and the roof of slate laid on concrete slabs. Trimmings are of Ohio marble. All floors are finished in terrazzo except those of the private rooms which are hard maple. The bases are terrazzo coved and have been set flush in plain and elevation.

In the basement wings are the machinery sections, and in the center basement are located the main kitchen, refrigerators, nurses' dining

The new hospital building of the Cambria Steel Company at Johnstown, Pa. This company claims the distinction of erecting the first industrial hospital in the country.

Off the solarium on third floor is a gymnasium with reconstruction outfits, occupational therapy equipment and facilities for massage work.

The x-ray department of the hospital

room, and storage rooms. On the main floor of the north wing are the receiving rooms and out-patient department. In the south wing are the private patient rooms, and in the center bay, the superintendent's suite, main office, doctor's office and two large reception rooms for visitors. Spacious halls add to a pleasing interior.

On the second floor wards are located in each wing, also a special ward in the administrative bay all equipped with diet kitchens, sterilizing rooms, nurses' stations, recovery rooms, patients' clothes' rooms, lavatory and bathrooms of the best sanitary type. The operating suite, the laboratory and x-ray department are also on this floor.

On the third floor are located an open air solarium, enclosed solarium and gymnasium; also a room for a McKenzie reconstruction outfit, occupational therapy and massage work is found.

The building is equipped with a modern elevator with double exits, an enclosed fireproof stairway which runs from basement to third floors, two enclosed fire escapes, and one outside fire escape. Each floor is equipped with fire pressure system and hose connections fed from the water lines of the company. The building is also thoroughly equipped with fire extinguishers. The heating system is direct steam, high pressure type, from the main boiler plant of the Cambria Steel Company, the pressure being reduced to service required by a control unit at the basement entrance.

Every room and every department are equipped with a vacuum and a plenum system of ventilation which permits the temperature of the hospital to be the same rating throughout. The drinking water is sterilized, filtered and ice-cooled by a Forbes

drinking fountains in all parts of the hospital. An ice machine which makes ice for general hospital use has a brine circulating system for cooling the refrigerators on the different floors. Electric lighting and power are furnished by the Cambria Steel Company, and are of both AC and DC type, modifications in phase and voltage being possible by a necessary motor generator and transformer. Both phase and voltage may be controlled by works or city service, each available at all times.

The modern type of steel cupboards, closets, blanket warmers and lockers which calls for built-in construction, has been installed so that no corners, or dust-gathering shelves are found in any part of the hospital from the basement to the top floor. The halls and stairways show flush walls and no projections, all door bucks staying flush with walls even at sill entrances.

In addition to the nurses' home and hospital, which have been newly constructed, there are quarters for the laundry and help, newly renovated and adapted for service in accordance with the latest ideas. The hospital can be reached from all departments of the company by direct telephone connection. Ample ambulance service is also available, and a complete staff of surgeons and nurses is always on duty.

The hospital is located near the Pennsylvania Railroad station on a hill known as Prospect, and is within ten minutes' ride of the farther point of the works. The flexibility of the system is such that in case of emergency 100 patients can be cared for, and in ordinary times from sixty to seventy. When racial or other factors enter, isolation is possible without additional expense. From the main hospital the various first-

Thirty student nurses are housed in this new residence

sterilizing plant in the basement, then circulated to

aid stations in the works are directed and the nurses at these stations are in constant communication with the hospital day and night.

### Pennsylvania Industrial Surgeons Meet

The sixteenth conference of Pennsylvania Industrial Physicians and Surgeons met November 17 at Pittsburgh, under the chairmanship of Dr. Francis D. Patterson, chief, division of industrial hygiene and engineering, Pennsylvania department of labor and industry, Harrisburg.

The program was composed of the following addresses: Address of welcome by Clifford B. Connelley, commissioner, department of labor and industry; industrial tuberculosis by Dr. F. S. Kellog, physician Western Union Telegraph Company, Pittsburgh; factory ventilation, Dr. C.-E. A. Winslow, professor of public health, Yale University, New Haven; adequate sickness records of lost time in industrial establishments by Dr. L. R. Thompson, surgeon-in-charge, division of industrial hygiene and sanitation, U. S. Public Health Service, Washington.

Dr. Lightner Witmer, professor of psychology, University of Pennsylvania, spoke on psychological tests that aid in determining the industrial efficiency of the worker. Dr. Frederick L. Van Sickle, executive secretary, Medical Society of Pennsylvania, talked on revamping state medical legislation; and Dr. R. R. Sayers, chief surgeon, U. S. Bureau of Mines, spoke on the care of the injured miner.

The Tennessee State Board of Health in conjunction with the U. S. Health Service will issue a series of weekly letters pertaining to malaria. These letters will be published in the county papers in the western division of the state.

# The Irreducible Minimum in Industrial Accident

BY SUSAN P. MOORE, ASSOCIATE EDITOR, THE NATION'S HEALTH, CHICAGO, ILL.

THE average man who is overtaken by a disease regards the matter as an entirely fortuitous occurrence. In such an event he thinks of himself as an unfortunate victim of circumstances and does not take the trouble to analyze the situation as the natural outcome of a combination of factors of temperament, habit, inheritance, and contact. Meanwhile a progressive program of preventive medicine finds its chief obstacle in this passive acceptance of a certain inevitableness in the occurrence of disease.

The same fatalistic attitude is encountered in the field of accident prevention. When the engineer has finished his job of installing safety devices he can be credited at most with forestalling not more than from 25 to 33 per cent of industrial accidents. The rest he breezily charges to the unpredictable "personal equation" represented by the individual workman and, barring some educational work in the form of a few more or less effective posters and some printed or spoken propaganda, the average plant manager at this point throws up his hands and shifts the responsibility.

But dodging the issue does not lessen the burden, and scientific organization must perforce face the problem of the preventable accident. The individual workman cannot, by trial and error, discover for himself the most favorable conditions for the work he has to do. They must be the subject of inquiry by the management. Organization of industry according to the basic principles governing human labor is economical organization, and accident prevention is peculiarly susceptible to the benefits of scientific control.

## Defines an Accident

It is time that the definition of an accident as a "non-essential circumstance or attribute" should replace the notion that accidents, being unforeseen, are therefore unavoidable. In point of fact, accidents do not "happen." They are reducible to laws; to a marked degree they are predictable; they are prone to affect particular groups and definite types of people. They even seem to run in some families. The fundamental necessity in accident prevention, then, is for the management to recognize causal relationships, to admit that every accident carries cul-

pability somewhere, and that contributing conditions call for analysis and eradication. It may almost be said that the fitting of guards to dangerous machines is the lesser part of the safety program. At least it is quite as essential to analyze the workman and the job as it is to supply the mechanical safeguard and it is of the highest importance to recognize in the working personnel the adventurous types whose mental make-up unfits them for hazardous positions or mechanical routine. This need is finding expression in the organization here and there of schools for foremen as it is coming to be considered that the proper handling of craftsmen rapidly develops the novice into the skilled workman, and at the same time makes for the initiative and cooperation which is everywhere so much desired.

There has, however, been very little discussion of the need of training for the rank and file of the men. It is well understood that conformance to the general laws of mechanics is an indispensable preliminary to the use of any machine, but for the most part unintelligence has marked our handling of the human motor. Only a self-contained, properly trained workman can be depended upon to meet the thousand and one adjustments of the work-a-day world. Then why is not more effort devoted to the production of skilled operatives?

Far more often than is generally appreciated the underlying cause of accident is fatigue or clumsiness or inexperience on the part of the operative. A detailed inquiry into a series of one thousand compensated accidents to women<sup>1</sup> in the state of New York brought out that fact that 18 per cent of the injured operatives had been with the employer less than a month; 50 per cent, less than six months; 63 per cent less than a year. Sixty per cent of these casualties affected workers under twenty-five years of age, and thus represented a greater economic loss by reducing the working period of the younger group. A heavier toll fell upon the married group,—those who probably suffered undue fatigue because they were doing double duty as home makers as well as wage earners. Health conditions, general fitness for the job, experience, fatigue,—all enter into the problem.

The health aspects of the question are beyond the bounds of this discussion excepting as output, tenure of the job, and contentment must be considered to hinge upon due regard to physiological requirements in working conditions, but there is no valid reason why the valuable findings of Watson on economical methods of learning and on the general principles affecting human adaptability should not be applied to industrial processes and ultimately effect a reduction in industrial accident. Intelligent handling and the gradual induction to the job would undoubtedly make for precision of movement and accuracy of work. The intricacies of industrial processes, the haphazard choice of operatives, and the casual introduction of the workmen to their specific work are circumstances that favor accidents and their paucity bespeaks a degree of adaptability that does the average workman credit.

An undue proportion of industrial accident falls upon the untrained and unskilled and those at the lowest rung of the wage ladder. The cost of the raw recruit is not paid for only in accidents, however, for the work done per day by the apprentice averages 15 per cent less than that of the skilled workman and represents a corresponding expenditure of about 65 per cent more energy. The added element of fatigue alone, with its characteristic lack in precision of movement serves to promote accidents, while the amount of excess work done (actual manual work) and the number of false steps taken can be estimated on the basis of the heap of discarded models which litter up the workshop.

The men are best trained on the job, particularly where the movements are complex and the work exacting. Skill acquired in preliminary training along other lines is not necessarily transferable; at least we are forced to admit that the value of our formal methods of training has been greatly overestimated. Certainly the leaders of industry are for the most part industrially trained. A. W. Forbes has recently come out with a scathing arraignment of recent attempts to teach a vocation in school. How many opportunities are open for learning on the job it would be difficult to say, but they should be utilized to the utmost for their educational possibilities.

<sup>1</sup> I. Nelle Swartz: *The Nation's Health*, June, 1921.

Watson lays particular stress upon economical methods of learning and Pyle, working with typical groups, reports on error percentages which must in industry be regarded as catastrophe potentials. The slow group, that is, those gradually inducted into a given process, in every case produced more work with greater freedom from error than the ones in whom the process of learning was unduly "speeded up." Spasmodic variations were in every case signs of bad work and undue expenditure of energy. Part of the business of education is to supply thought-out successions of movements so that re-

sponse can be more or less automatic. Faulty habits are easily remediable under direction. Effort should be made to eliminate those attitudes or motions of the body which are valueless or even detrimental. The job should be investigated as to tools, posture, unnecessary oscillations of the body and irregularity in the movements of the limbs. Undue strain of any part of the body should be avoided and the job charted, at least as to external conditions, so that the apprentice would have ample opportunity for intelligent learning. Amar concludes that on the average one-third of the available energy of

man is wasted; that is, methodical organization could be expected to increase efficiency in that proportion. Industry pays for inefficiency, and the toll of haphazard learning is exacted in accidents and spoiled work, not to mention the price paid in loss of health and efficiency. When the mechanical features of inspection and protection are perfect, preliminary training adequate, and supervision scientific, then and then only may the unpredictable, unpreventable accident be charged to the convenient category of the "personal equation." Interest in output gives place to interest in working methods and in the worker.

## Conference Board of Physicians in Industry\*

AT the thirty-fourth meeting of the Conference Board of Physicians in Industry, held in New York City, September 16, 1922, many questions of interest and importance were discussed. Of particular interest was a report on the use of a 2 per cent solution of mercurochrome in the place of iodine for the treatment of industrial injuries. By the use of this material there had been no infections, much less discomfort was caused the patient, and less staining of the patient's skin was noted than when iodine was used. As this had been tried in only one industrial dispensary, it was felt that a more extended use of this solution should be had before its adaptability to general industrial work was demonstrated.

Dr. John J. Moorhead reported that some experiments had been carried out at the Post Graduate Hospital, New York City, in which it was found that the application of iodine to the unbroken skin of animals resulted in a sterile surface; while other forms of cleansing, such as soap and water with vigorous brushing, failed to give sterile results. He stated that the time element in the application of disinfectants to wounds is of the greatest importance. If an open wound can be disinfected within the first eight hours, much better results are produced than if the initial disinfection is delayed beyond this time. Experimental work shows that after about eight hours there is a considerable increase in the number of bacteria present in the wound secretions

and that this number continues to multiply for about three days, after which there is a marked reduction in the number present for a short period, then another increase in numbers for a similar three days, this process being continued until and unless adequate disinfection is applied to the wound.

While it was felt that in certain types of injury, such as extensive burns, other disinfectants are of value, it was the opinion of the conference that, for general all around wound disinfection purposes, iodine still holds first place.

### Benzol Poisoning

Dr. R. S. Quinby presented a paper on benzol poisoning in which he discussed the chemical composition, properties, and use of benzol and similar products. He pointed out that as it is also known as benzene, which has the definite chemical formula of  $C_6H_6$ , it is frequently confused with benzine, a complex mixture of unknown chemical composition. Benzol is derived from coal tar, while benzine is derived from petroleum.

Benzol is widely used as a starting substance in the manufacture of coal tar dyes, also used in the manufacture of explosives, artificial perfumes, drugs and photographic chemicals. Owing to its high solvent property, it is useful in rubber and artificial leather industries and in the manufacture of quick drying paints.

Industrial poisoning arises for the most part from inhalation of fumes and experience has shown that the relative toxicity of pure and commercial benzol seems to lie in the connection between their boiling points rather than to any impurities contained in commercial benzol. The

benzols with lower boiling points give out more vapor and are greater hazards.

Individual susceptibility to benzol poison varies. Females are more susceptible than males. The very young, the very old, and those with organic diseases—particularly heart and kidney diseases—are more susceptible. Addiction to alcohol and excesses of all kinds increase susceptibility. Hot, humid weather conditions with poor ventilation appear to exaggerate the hazard.

Prior to 1914, only three fatal cases had been reported in American medical literature. Since that time a considerable number of accidents of both acute and chronic cases of benzol poisoning, fatal and non-fatal, have been reported in this country and abroad. Some rather startling cases have been reported, such as the following from England: A tank car was unloaded, washed with water, steamed out, left filled with water for twenty hours, then washed twice, again filled for twelve hours with water, finally left empty for ten days with a sixteen-inch manhole open. A man who was then sent into the tank collapsed and, although he was revived, one of his rescuers died.

In mild cases, symptoms of benzol poison consist of vertigo, tinnitus, nausea, slight flushing, and a condition resembling inebriation. Severe cases show symptoms of central nervous system affection, muscular tremors, spasms, livid clammy skin, nausea and vomiting, headache, severe dizziness, etc. If the condition is prolonged there are subcutaneous hemorrhages and hemorrhages of the mucous membranes, death resulting in a state of delirium, unconsciousness, and convulsions. Marked blood changes also

\*Conference Board of Physicians in Industry. Organized for cooperative effort in introducing into industrial establishments the most effective measures for the treatment of injuries or ailments of employees; for promoting sanitary conditions in workshops; and for prevention of industrial disease. Report authorized by Drs. J. J. Moorhead, chairman, and Frank L. Rector, secretary.

occur, such as progressive reduction in the number of leucocytes, increase in the coagulation time of the blood, and rapid weak pulse. The reduction in hemoglobin and leukocytes is very marked, the hemoglobin measuring as low as 35 per cent, while the leukocyte count may be reduced to as low as 750. There is also a marked reduction in the number of red cells present.

The prevention of benzol poisoning consists in reduction in the use of benzol or the removal of fumes by artificial ventilation on the one hand, and rigid medical supervision of those exposed in any way, on the other. Less toxic solvents may be substituted for benzol in many operations. Ventilation should consist in a change of air at least thirty times an hour,

forced in at the ceiling level and exhausted at the floor. Air velocity toward the floor should not be less than six feet per minute. If, however, the benzol is used in a warm solution, the air should be exhausted on a level with the working plane or slightly above it, as the warm fumes will not settle as readily as when cold.

Medical supervision should include a physical examination at least every four weeks in addition to a differential blood count, an estimate of the coagulation time of the blood, and a careful search for any indications of hemorrhage. Marked reduction in white blood cells or an increase in coagulation time should indicate a transfer to operations when benzol is not used. Especially susceptible individuals should not be employed

where benzol is used. Treatment is largely symptomatic except that frequent blood transfusions seem indicated in chronic cases. Prompt removal from contact with benzol is always indicated.

It is realized that benzol will probably find an increased usage in industry because it is relatively inexpensive and highly solvent. It is felt, however, that its usage can be made relatively safe under certain conditions by a knowledge of its dangers, the use of proper ventilation, plus rigid medical supervision of those exposed. These facts should be carefully considered by all industrial physicians who in any way have anything to do with the use of this material in their manufacturing establishments.

## Industrial Dentistry and Oral Hygiene

By R. I. HUMPHREY, D.D.S., CHIEF, DENTAL DEPARTMENT, INTERNATIONAL HARVESTER COMPANY, CHICAGO.

IN considering the subject of industrial dentistry and its value to general health, one experiences a sense of disappointment at the extremely bad condition commonly found in the mouths of people who are working in our densely populated centers. Only those dentists who have been engaged in industrial work during the past few years fully realize the extremely insanitary condition which actually exists. Oral hygiene among this element of our population has been so neglected that one sometimes wonders that the condition is not even worse than we find it to be. Many of these people are illiterate, and they are wholly uninformed in the field of oral hygiene. The importance of such a common operation as brushing their teeth has never been urged upon them, nor have they considered it necessary to consult their dentists for prophylactic or constructive dental care, except perhaps as the result of an emergency such as a pulpitis or an acute abscess. The only treatment many of them received on such occasions was the removal of the offending tooth.

In seeking an explanation of this most unhealthy condition, it is pertinent to mention the fact that more than 50 per cent of the employees whose mouth condition we have recorded are foreign born, and that more than 90 per cent of this number come from rural districts. From these findings it appears people of rural districts are considerably less informed regarding mouth hygiene, and more especially among the foreign born.

If preventive methods are to safeguard public health industrial oral hygiene needs to be added to the routine care we are now giving to the mouths of school children and to the service rendered better educated, more or less well-to-do people who are receiving periodic prophylaxis. We know that it is a comparatively simple matter to serve patients who have been taught the importance of oral hygiene from childhood, and who have the means to secure first class service. However, this is not the case in industrial groups. The industrial dentist must first in some way bring to the minds of the people he serves the importance of keeping the mouth clean, and it is this particular phase of the work which seems of greatest promise in industrial dental service. It is not a simple task to persuade all those adults with whom we come in contact to follow out a definite prophylactic program. However, the results of this work in the International Harvester Company have been encouraging enough to warrant the continuation of this service, and to supplement it by utilizing the support of more dentists in private practice.

Thus far the field of industrial dentistry has not received adequate support from physicians and dentists engaged in private practice. There are still a few private practitioners who hold that industrial work is robbing them of a livelihood, an untenable position, in view of the fact that the amount of constructive work it is possible to accomplish by men in industry

is very limited, even though the number of dentists engaged in this type of work were many times greater than at present. Furthermore, the benefits which ultimately accrue to the private practitioner through the education of employees along this line is very considerable. Convince the head of the family that the care of the mouth is highly important and he will naturally insist that other members of his family be properly cared for.

### The Teeth and Health

Physicians in industry are constantly coming in contact with chronic cases where oral hygiene has a direct bearing on the prognosis in the case. The close cooperation of physician and dentist in cases of this kind is absolutely necessary if satisfactory results are to be obtained. The cooperation that is possible in industry has demonstrated its value and is producing very remarkable results.

The following cases are typical of many which we have treated during the past six years:

*Case No. 1.*—Male, aged 35. Family and personal history negative. Patient complained of pain in muscles of neck and shoulders. Had not slept well for two weeks. Physician could find nothing which would account for the trouble. Oral examination revealed four deep pyorrhea pockets. Extraction of the affected teeth was followed by the immediate disappearance of muscle pain.

*Case No. 2.*—Female, aged 31. Family and personal history negative. Patient had complained of pain in stomach two years prior to examination. Physician sent patient to hospital for

observation. Diagnosis was made of probable gastric ulcer. Diet was recommended and after a period of six weeks patient returned to work feeling greatly improved. The same trouble recurring in about six months, patient was sent to general hospital a second time for diagnosis, at which time all the findings were negative except that six teeth were abscessed. The teeth were extracted and the patient returned to work. In six months the patient had gained twenty pounds in weight. Three years have elapsed since treatment, during which time there have been no symptoms of the old trouble.

*Case No. 3.*—Male, aged 37. Family and personal history negative. Patient complained of excruciating pain in left thigh of two weeks duration. Physician's diagnosis, sciatica. Examination of mouth revealed extremely septic conditions, including pyorrhea, abscesses, and caries. All teeth were extracted. A very rapid improvement ensued and there has been no recurrent trouble during the past four years.

Much has been said regarding focal infections and its relation to general health, and in some cases perhaps there was some exaggeration. However, after handling several hundred of these patients, it is really astonishing to note the vast improvement that is uniformly registered in the general health following the elimination of mouth infection.

It is a somewhat debatable question as to just how far we should go in the way of restorative work in the indus-

trial field, because conditions in different localities and in different industries are not the same. However, if the educational feature which always predominates is to become effectual, such service must be rendered as the immediate relief of pain, cleansing of teeth, extractions, abscess treatment, examination, and at least a limited amount of filling and plate work.

The two most vital points always to be considered by the dentist in industry are the prevention of pulp exposure and the prevention and elimination of peridental infection. When all is said, industrial oral hygiene does not differ from any other field of dentistry, in that it is always sought to render the maximum service. It has been the aim from the very outset of this most worthy movement to give the greatest service possible that is compatible with existing conditions.

It has been a source of considerable satisfaction to know that employers have co-operated very thoroughly in industrial dentistry and we hope that our dental organizations will take a more active and constructive attitude in helping us to render a better and more complete service to a mass of human beings who are badly in need of dental service, and who were almost entirely neglected until industrial dentistry was inaugurated a few years ago.

Underwood and Underwood.  
Dr. H. E. Howe of Washington, chairman of the committee on work-periods of the Federated American Engineering Societies.

which results from leisure properly expanded is very well worth while to the employer will also be new.

Another observation which is noteworthy is that referring to the part which labor-saving devices and equipment in good condition play in making possible the increased intensity of operation which under proper management may be expected to give an increased production in three shifts over that in two shifts which repays extra cost. One cannot read the report carefully without realizing that any of these forward steps depend primarily upon capability and skill in management, no less than upon hearty cooperation on the part of both labor and management.

It may take a long while to bring many industries to the shorter shifts, and indeed there may always be some kinds of work on the twelve-hour basis. The committee responsible for the report very much hopes that the work presented may be a contributing factor in improving labor and social conditions.

One of the most gratifying results to the engineer, was the practically unanimous attitude of the press in commending the spirit of the inquiry, which had been carried out by the engineering profession solely with the aim of public service.

Horace B. Drury, formerly of the faculty of Ohio State University, who with Bradley Stoughton, chairman of the iron and steel committee of the American Institute of Mining and Metallurgical Engineers, directed the field work of the investigation, asserted that the change from the twelve to the eight-hour day, so far as it has been tried, "has secured results sufficient to compensate in whole and part for the extra cost involved."

## The Eight Hour Work Day

THE engineers who, after two years of effort, have just completed a national investigation of the problem of the twelve-hour day are convinced that more leisure will make the working man better off and that both employer and employee will benefit by the shorter day, which since the war has spread over Europe and is being introduced in Japan, Canada, Africa, and India.

Dr. H. E. Howe of the National Research Council, chairman of the committee on work-periods of the engineering societies which has investigated over forty continuous industries, states that the report which has been made on the twelve-hour shift in American industry under the auspices of the Federated American Engineering Societies will prove an unusual and valuable document for several reasons. It will be news to many people that there are still so many industries in which the long shift is in vogue. The report contains suggestions which should lead to extensive

experiments in the near future.

"It is a novel suggestion," states Dr. Howe, "that in changing from two to three shifts in continuous industries the men be paid the same rate per hour, thereby establishing a basic wage equivalent to two-thirds their income on the longer day, and yet supplement this with a bonus graded upon performance, which would make it possible for the more proficient to make their income equal that before the change." Dr. Howe's statement follows:

The references made to the value of leisure ought to start many managers thinking along lines new to them, and give rise to considerations which may break down some of the prejudices against a change in the length of shift. It involves something of the spirit of service, for in many cases steps will have to be taken to teach labor the real value of leisure and the best ways of employing it.

That labor can earn something in leisure hours by doing for itself many odd tasks which are ordinarily paid for has not occurred to many, while the thought that the net gain

Increased efficiency, he ascribed to "better physical and mental condition of the men, better class of men attracted, better conduct of operation,

more uniform operation, better quality of product, less fuel used, less waste, less repairs to equipment and longer life of apparatus."

The eight-hour day, produces better morale, resulting in less absence and tardiness, less shirking and better discipline.

## A New Instrument for Sampling Aerial Dust

TWO methods of dust sampling that have in the past revealed serious inherent difficulties have been combined in a new device that promises the efficiency of impingement together with the analytical advantages of a liquid sampling method. This ingenious yet simple apparatus is the invention of Leonard Greenburg, assistant sanitary engineer (R), U. S. Public Health Service and George W. Smith, junior physical chemist, U. S. Bureau of Mines. The following description of the impinger and account of the preliminary tests appeared in a recent report of investigations, issued by the U. S. Bureau of Mines.

The Bureau of Mines and the Public Health Service, cognizant of the importance of dust in the causation of pulmonary disease, have conducted numerous studies on the quantity and nature of dust in mine and factory air. Several of these studies have appeared as technical papers of the Bureau of Mines, and as contributions to the weekly reports of the Public Health Service.

For the purpose of sampling the dust in the air, the Bureau of Mines has made use of the sugar tube method. Briefly, a sugar tube consists of a glass tube 2 $\frac{3}{8}$  inches in diameter and 5 $\frac{1}{2}$  inches long, one end of which is constricted to  $\frac{1}{8}$  inch outside diameter, for connection to an air pump by means of suitable rubber tubing. In the glass tube is placed a layer, 1 $\frac{1}{2}$  inches deep, of sized granulated sugar weighing 100 grams. By means of a suitable pump, air is drawn through the sugar tube at a rate of approximately 1 cubic foot per minute. The dust is retained in the sugar tube, which is then stoppered and sent to the laboratory for analysis.

The Public Health Service makes use of the Palmer water-spray apparatus for the sampling of dust. This method consists essentially of a motor with an exhaust fan to which is connected a pear-shaped glass bulb, at the base of which is a water trap. Approximately 40 c.c. of distilled water is placed in the trap. When the motor is started, air is drawn through the water seal, thus breaking the water into a spray, which washes the dust from it. A Pitot tube registers the rate of air flow, which is controlled by means of an outlet valve at the top of the instrument. After a suitable quantity of air has been sampled, the water is removed to a flask and sent to the laboratory for analysis.

A third type of instrument devised by one of the members of the South

African Miners Phthisis Commission is now engaging some interest in the United States. This is known as the Kotzé konimeter. It consists of an air cylinder and piston actuated by a spring, and is so arranged that on release of the piston a known volume of air is impinged at high velocity against a vaselined plate. The dust spot so produced is examined under the microscope, and count is made of the number of particles, but with this instrument no estimate can be made of the weight of the dust present.

The apparatus that the authors have devised, and a description of which follows, makes use of the principle of impingement of the dust-laden air at high velocity on a wetted glass surface, together with that of bubbling the air through a liquid medium. This apparatus consists essentially of three parts; a hand pump or electrically driven blower; a flow meter, or other suitable means of measuring the air passed through the instrument; and the dust-collecting device.

The dust collector consists of a conical tall form, flat-bottomed assay flask or precipitating jar of 500 c.c. capacity, provided with a two-hole rubber stopper. In one of these holes is fitted a suitable outlet tube which is connected with the flow meter, and the latter in turn is connected with the exhaust apparatus. In the second hole of the rubber stopper of the dust collector is placed an impinger tube (of glass in the present type, but this may later be changed to a non-corrosive metal)  $\frac{5}{8}$  inches in diameter and 9 $\frac{1}{2}$  inches long. This tube is open at the upper end, and is provided with a flat bottom. The bottom is pierced by 15 holes, each approximately 0.8 mm. in diameter. Projecting from the bottom of the tube at its periphery are three lugs each 0.8 mm. long, the purpose of which is to keep the bottom of the tube always 0.8 mm. from the bottom of the flask.

Manipulation of the instrument during sampling is easy. At the laboratory enough sampling flasks are cleaned thoroughly and filled with distilled water to the graduation mark (at present 300 c.c.). These flasks are then stoppered and taken to the place at which samples are to be collected. The apparatus is set up and the sampling is begun by starting the pump. After a sufficient length of time determined by judging the amount of dust in the atmosphere, the pump is stopped and the impinger tube stopper is removed. This tube is rinsed with a small quantity of water which is allowed to drain into the sample just taken. The flask is stoppered, and is now ready for the laboratory examination.

The efficiency of this dust sampler

has been tested by an apparatus, in use at the Bureau of Mines experiment station; so constructed that air laden with dust or tobacco smoke may be passed through it and a comparison obtained between the incoming and outgoing air. The quantity being known of the dust-free air necessary to dilute a sample of the incoming air to make it match, by Tyndall effect, the air emerging from the sampler, an efficiency rating for the sampler tested may be obtained.

When tested with tobacco smoke in the manner described above, this apparatus was found to have an efficiency of 66 per cent. In a similar manner it was tested against silica dust, a majority of the particles of which were under one micron in diameter. In this test the apparatus developed an efficiency of 93 per cent. The apparatus was then tested against silica dust on a gravimetric basis and the emergent air was filtered through a Whatman No. 42 filter paper. The dust in the flask was then filtered through a Gooch crucible and weighed. On the basis of the weight of the material on the filter paper (known to be 95 per cent efficient against this particular dust and making a correction for this) the dust sampler proved to be 96 per cent efficient.

In Technical Paper 278, of the Bureau of Mines, tests similar to the above are quoted on the standard type sugar tube of the Bureau of Mines. These results are clearly brought out in the following table.

	EFFICIENCY, PER CENT	
	Sugar Impinger tube*	Sugar Impinger tube*
Smoke test, optical....	66	35
Silica test, optical.....	93	75.6
Gravimetric silica dust..	96	87.0

\*Approximate averages.

The analytical procedure necessary when using this new impinger-bubbler apparatus is almost identical with that employed with the Palmer apparatus. As sugar is not employed, the new apparatus possesses the advantage over the sugar tube method in having very low control errors, being, therefore, much simpler in laboratory manipulation during analysis.

Studies are being continued on several of the factors entering the design of this instrument with a view to determining its value for general industrial and mine use.

A study of social activities in senior and junior high schools is being made by Alice F. Cullen, 144 West 4th Street, Oswego, N. Y. According to announcement in the *Journal of Education*, Miss Cullen will be glad to receive information from others interested in the subject.

# Recent Compensation Decisions

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

OCTOBER 17, 1916, John Watson sprained his left ankle while in the employ of the defendant. He was treated, an infection followed, two operations were performed and finally in May 19, 1919, when a post mortem examination was performed, a tuberculous condition and a pus cavity were found in the injured ankle bone. After his death the widow made application for further allowance. The Supreme Court of Pennsylvania, March 6, 1922, in passing on the case, declared that Watson died within the period of 300 weeks specified in the statute and, "if his decease was attributable to the injury received, his widow is entitled to compensation." It is "evident that Watson was suffering from disease (though apparently in good health) at the time of the injury and the immediate cause of his death was tuberculous peritonitis. It was hastened, however, by the osteomyelitis which developed in the left ankle. Indeed, the post mortem examination of the bone showed death might have resulted from the infection of the foot alone, though Watson had not been in bad physical condition."

The judgment of the Workmen's Compensation Board was affirmed.—*Watson v. Lehigh Coal & Navigation Co.* 116 A. 889.

THE deceased was afflicted with incipient tuberculosis of the lungs in the fall of 1917. He left for a time and returned, resuming work for the defendant employer. On May 1, 1918, he fell from a staging, worked at intervals until June 10, when hemorrhages developed and labor ceased. The tuberculosis became active and he died April 4, 1919. The question is whether in fact death did ensue as a result of the injury, which the chairman so found upon what constituted some competent evidence, drawing reasonable inferences from proved facts. The award of the Industrial Accident Commission was affirmed by the Supreme Judicial Court of Maine, June 8, 1922.—*Jacque's Case*, 117 Atl. 306.

TO recover compensation for an employee's death under the Workmen's Compensation Act, it is not only necessary to show that

death resulted from an injury in the course of employment, but also that death resulted from injuries arising out of employment, according to a decision of the Court of Appeals of Maryland, January 10, 1922.

Victor Webster was employed as a carpenter upon a vessel in construction by the Shipbuilding Company. Webster was employed on one of the top decks. "It was while there that he fell from said deck to the ground below, causing a compound fracture of the left side of the skull, extending to the back of the brain, from which injury he died on the same day, . . . while rising up from laying down tools, (he) stepped on a rivet, which caused the patient to fall backward off the ship, falling a distance of 45 feet, striking his head, below."

The U. S. Fidelity & Guaranty Company in contesting the claim of compensation awarded by the State Industrial Accident Commission declared that:—(1) the injury did not rise out of or occur while in the course of employment; (2) that the death was not the result of an accident. Among other things the appellant asked two questions: "Was the death of Victor Webster on the 20th day of April, 1920, due to a fall occasioned by a vertigo or epileptic fit? The court declined to answer the question because its determination was not material to the decision of the case. To a second question: "Was the death of Victor Webster on the 20th day of April, 1920, occasioned by an injury received in the course of and growing out of his employment," the reply was "Yes." The appellants' prayer asked the court to declare the law that if the death was the result of a fall occasioned by a vertigo or epileptic fit, "then the verdict must be for the defendant, notwithstanding that the court further found that he was engaged in work at the time, growing out of and in the course of his employment."

This prayer was refused by the court. The appellants conceded "that the decedent at the time of his death was engaged in an extra hazardous occupation, and that his death resulted from an accidental personal injury sustained by him in the course of his employment," but they deny that his death resulted from an injury arising out of this employment.

To entitle the claimant to compensation it was not only necessary that it be shown that death resulted from an injury sustained by the employee in the course of his employment, but also that his death resulted from injuries arising out of his employment.

The refusal of the prayer denying compensation, if the vertigo or fit "contributed" to the fall, was held proper, since the injuries caused by the fall may have arisen out of the employment, even though the vertigo or epileptic fit contributed to the fall. "We have found no cases in which the claimant has been refused compensation when the accident resulting in injury or death of the employee was not caused solely by the physical disability of the employee, or where it contributed only to the accident."—*Baltimore Dry Dock & Shipbuilding Co. v. Webster*, 116 Atl., 842.

THE Court of Appeals of Kentucky, May 9, 1922, held that an employee who was engaged in felling a tree assumed the risk of being injured from the fall of such tree, although he was deaf, in the absence of an allegation that his mind was affected or that his eyesight was impaired.—*Mocabee v. Horbesen Walker Refractories Co.*, 240 S.W. 380.

AN INJURY which aggregates a chronic appendicitis has been held compensable by the Supreme Court of Michigan, June 5, 1922.

A laborer in a foundry was assisting in pouring molten iron. The ladle slipped and the plaintiff was so wrenched or jerked that he developed a pain in the region of the appendix. The first attendant physician declared the man overcome by the heat of the foundry room and treated him accordingly at the hospital. Later another physician was called in and treated him for appendicitis and operated. The finding of the board concerns "An accidental personal injury under the act, from the testimony of the plaintiff and his fellow workmen. . . . The finding has evident support and is therefore sustained." The facts that the plaintiff's disability "may have resulted from the accidental aggravation of a chance ailment, and that he may have been predisposed because of disease to this form of attack, have nothing to do with the question of whether what befell him is to be regarded as an accident."—*Fritz vs. Rudy Furnace Company*, 188 N.W. 528.

## Better Hours for Labor

**I**N trend with the recognition of the evils of the long working day and the seven-day week is the statement of John D. Rockefeller, Jr., in the November *Survey Graphic*.

Mr. Rockefeller denounces the twelve-hour day and the seven-day week and states it as his belief that the eight-hour day and six-day week should be adopted as the labor standard. His statement follows:

I believe that generally speaking the twelve-hour day and the seven-day week should no longer be tolerated in industry, either from the viewpoint of public policy or of the industrial efficiency; I believe that both have been proved to be unnecessary, uneconomic, and unjustifiable. As a matter of general policy, subject only to the demands of occasional emergency, modern industry is justified in accepting the eight-hour day and the six-day week as a labor standard toward which all parties interested should steadily press. Even in those industries where the continuous process is an inevitable feature, the routine should be so adjusted that the employees can have at least one day's rest in seven and can obtain that share of leisure for self-development which accompanies the work-day of approximately eight hours. While the adoption of these standards may and doubtless will at first entail increased costs of production, I am confident that in the long run greater efficiency and economy will result, and that from the outset public opinion will support any industry which installs them. The same sentiment will eventually bring into line the less scrupulous and less enlightened elements in every competitive industry.

With regard to living conditions there can be even less room for argument or division of opinion among men of clear vision and humane mind. Even in isolated locations like mining camps, it is not only possible but necessary that reasonable provision should be made for the health, comfort, and contentment of those who may labor there in behalf of the entire community. The oil fields, to be sure, suffer difficulties even greater than the coal mines, being not only temporary but speculative in their output. Even with this allowance the environment is certainly subject to amelioration and to such provision for home and recreation life as will promote the well being of all those concerned.

I have never believed that these things should be provided for working men and women either as a result of chance generosity or deliberate paternalism. Quite aside from the fact that, in my judgment, they represent the soundest economic policy, they are due the employee as a matter of common justice, required by the basic fact that man is a human being first and a member of industry afterward. As a private citizen and individual stockholder, I have

never hesitated to state my position on these points with all the clearness at my command. I have not wittingly lost an opportunity—so far as a minority stockholder may do so—to reinforce my position on the general policy with action that would be most concrete and adequate. I have done so, moreover, where changes urged by me involved competitive burdens and consequent anxiety to responsible managers, but I have never seen reason to regret any advance thus obtained or to modify the grounds on which they were urged. On the contrary, I would reaffirm the belief that sooner or later all such added burden is balanced by the increased efficiency and contentment of the laboring force and that less generous directors of industry in due time will inevitably follow the same course, if not through choice then under compulsion of public opinion.

In pursuance of this policy, some of the problems which have to be faced and many of the evils which should be removed are deeply rooted, sometimes within the processes of an entire industry. To my mind, however, where the right course is clear, difficulties in the way do not excuse inaction, but rather should inspire a more vigorous determination. So far as concerns the discharge of my own responsibility as a stockholder for better industrial conditions and relations, I have made special provisions for assistance in just such tasks as these, which are sometimes onerous, often perplexing, but always close to my heart. To that end I welcome every aid from whatever source, as men of like mind and common purpose try to raise industry to a level of public service and thereby to make the world a better place for all men to live in.

### Atmosphere and Comfort in Work Hours

More care should be taken to arrange atmospheric conditions in factories to suit the nature of the work being done. The heavier the work, the higher will be the cooling power of the atmosphere required to maintain comfort. Observations made in many workshops where vigorous muscular work is done show that the cooling power of the atmosphere as measured by Hill's kata-thermometer was far too low. In these shops covered by recent experiment no one seemed interested in the matter and no one was sufficiently skilled to regulate the ventilation in order to produce a suitable cooling power.

In the current issue of the *Journal of Industrial Hygiene*, Leonard Hill and J. Argyll Campbell report a series of physiological experiments which prove that more attention should be paid to the atmospheric

conditions in work rooms. The matter is much more important than is generally appreciated because most of the experiments heretofore recorded have been carried out with the subjects very lightly clothed and in atmospheres not under such ill-ventilated conditions as obtained in the average workshop. Under perfectly controlled conditions Hill and Campbell recorded the efficiency of the subject as measured by output, studied the energy expenditure in a given amount of work, and correlated the pulse rate and general comfort of the subject with a cooling power of the atmosphere. They conclude that cool conditions have great advantage over warm conditions, mainly because the heart is given less work to do, and bodily comfort is maintained when the cooling power is high. Some attention also was given to the cooling power that is required to maintain comfort at a given rate of work. They consider that the main advantage of cool conditions is in relief to the heart and that such relief keeps off fatigue and enables the individual to work longer hours in comfort and content.

### Vision: Its Relation to Industry

The need for protecting the eyes of the worker is sufficiently attested by the fact that approximately fifteen thousand persons in the United States, or about 13.5 per cent of the total blind population, have been rendered blind by industrial accidents. The actual economic loss from the incapacitation of this large group cannot be estimated. The eye is involved in 10.6 per cent of all permanently disabling accidents. Preventive methods strictly applied would materially reduce eye accidents.

Dr. Earle Fowler discusses in the *Iron Trade Review* means of prevention which in the American Steel Foundries factories have reduced eye accidents by 85 per cent. In working with commercial illuminant the amount of ultra-violet energy is not sufficient to make essential the wearing of special goggles. This protection is required in the oxy-acetylene process in steel making. The cobalt blue glasses often relied upon are not sufficient protection. The wearing of goggles is usually considered irksome by the workers, but their use is a most valuable protection. First aid services in factories where eye accidents are prone to occur is an important provision.

Eyework produces fatigue, the most

largely contributing factor being defective vision. An examination by a specialist of the eyes of ten thousand employees in various industrial and commercial establishments showed 53 per cent with uncorrected faulty vision. Another inquiry referring to 675 workers showed 58 per cent in need of glasses. Another study revealed that only 22 per cent of three thousand employees had normal vision. Twenty-one per cent of army recruits had to be discharged owing to eye defects. The industrial output of such cases is greatly decreased.

Prophylaxis consists in the provision of good lighting conditions. The placement of light as to sources and its diffusion has an immediate effect in the welfare of workers and in their output. The cost of good lighting would not exceed 0.5 per cent of the whole wages of industry in the United States, and expenditure in this direction could be expected to result in a positive increase of output.

### Safe Practices in Underground Ventilation

A recent report of investigation by R. R. Sayers of the U. S. Bureau of Mines gives the following summary of procedures useful in minimizing the hazards to which the underground worker is exposed:

(1) Miners who work in mines in which the rock contains a high percentage of silica and use dry mining methods have been found to be prone to pneumoconiosis. (2) Miners' phthisis or pneumoconiosis has been found to dispose to tuberculosis. (3) Good ventilation, wet drilling, and wet mining methods materially lessen the amount of pneumoconiosis. (4) Physical examination at regular intervals, at least once a year, followed by proper precautions by those found to be affected by pneumoconiosis or tuberculosis materially lessens their prevalence. (5) Some dusts, as those from the more soluble lead, zinc, or arsenic ores, may cause illness due to the toxic effects of the respective salts of these metals. The precautions mentioned in paragraph 3 are applicable here. (6) Air low in oxygen causes deeper and more rapid breathing and an increase in heart rate. If sufficiently low, unconsciousness or even death may result. (7) The flame of a safety lamp may be used to detect air low in oxygen. (8) Increased percentages of carbon dioxide in the air cause an increase in the depth and rate of respiration,

headache, dimness of vision, and tremor. (9) Carbon dioxide may be detected and the amount present determined by a special portable apparatus developed for this purpose. (10) Nitrogen, hydrogen, and methane have no toxic effect on the body but may act as diluents of oxygen and thus indirectly cause the effects of oxygen deficiency. (11) The flame of the safety lamp, or a Burrel detector, may be used to determine the presence of marsh gas. (12) Hydrogen sulphid and sulphur dioxide may occasionally occur in mines in sufficient quantities to be dangerous. In low concentrations they cause irritation of the eyes and respiratory organs. (13) The presence of hydrogen sulphid and sulphur dioxide may be detected by their respective characteristic odors. (14) Carbon monoxid (white damp) has caused the death of many miners. (15) The presence of carbon monoxid may be detected by its effect on canary birds or by the use of a carbon monoxid detector. (16) Animals without red blood are not affected by carbon monoxid. (17) High temperatures and humidities decrease the efficiency of miners and probably have a deleterious effect upon their health. (18) Good ventilation will prevent the ill effects of all gases referred to in paragraphs 6 to 17, inclusive.

### Health Survey of the Printing Trades

A health survey of the printing trades has been authorized by the International Joint Conference Council, representing both employers and employees. The Survey is intended to cover two years and will be nationwide. The work will include a thorough study of printing processes in their relation to health and of printing house conditions, possibly more or less detrimental to health and life. The investigations will be carried on in cooperation with a large number of governmental, scientific, and corporate organizations, including the United States Bureau of Labor Statistics, which will have charge of the major portion of the social and economic inquiries.

A large measure of cooperation is expected from the insurance companies, but especially from Harvard Medical School, Yale Medical School, the public health school of Johns Hopkins University and a number of state health and labor departments. Particular emphasis will be placed

upon methods of ventilation, air-pollution, lighting, eye-strain, posture and physique. The investigation will be made under the immediate direction of Dr. Frederick L. Hoffman, dean of the advanced department of the Babson Institute, Wellesley Hills, Mass., and the consulting statistician of the Prudential Insurance Company of America.

### Acute Rheumatism a Working Class Disease

The seriousness of acute rheumatism and its consequences is not generally appreciated. It is undoubtedly one of the great killing diseases, according to Robert Hutchinson, writing in the *Lancet*, not so much directly, though the immediate mortality of cases with carditis is very considerable, but indirectly through the permanent damage so often done to the heart. Apart from its effect on the death rate, acute rheumatism is the cause of an immense amount of disability. The observations of Dr. Hutchinson are particularly interesting as they bear upon rheumatism as affecting particularly the industrial worker. He states:

Acute rheumatism is essentially a working-class disease; I could count upon my fingers the cases I have seen in consultation in twenty years, whereas my wards both at the London Hospital and Great Ormond Street are always full of it. This special incidence of the disease has been pointed out before, but I can offer no explanation of it. In common, I suppose, with most of the profession, I now regard acute rheumatism as an undoubtedly infective disease, due to infection with one or more forms of micro-organism. But although infective it is certainly not infectious, and it is difficult to believe that over-crowding or defective nutrition can act as predisposing conditions. Inadequate clothing or sitting in school after getting wet may more probably have something to do with it, but even this explanation does not seem adequate. It has been suggested that the greater incidence among the working classes is more apparent than real, and due to the fact that the earliest signs of the disease are more promptly recognized in well-to-do families, with the result that it is nipped in the bud and does not go to the stage of serious manifestation; there may be something in this explanation, but again I am doubtful whether it covers all the ground. The fact remains that those who practise in industrial communities see most of the disease; those who labor at the other end of the social scale rarely meet it in a severe form.

The use of hydrocyanic acid has been forbidden by a decree in Germany.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Window Ventilation Preferred for Schools

### New York State Commission Issues Final Report on Air Conditioning

By C.-E. A. WINSLOW, CHAIRMAN, NEW YORK STATE COMMISSION ON VENTILATION.

THE New York State Commission on Ventilation was appointed by the Governor of New York June 1913, on the request of the New York Association for Improving the Condition of the Poor. The work of the commission was made possible by the assignment to its use of the sum of \$50,000 (later increased to \$75,000) out of a munificent gift made to the association by the late Mrs. Elizabeth Milbank Anderson.

The members of the commission, all of whom served without pay were: Mr. D. D. Kimball, ventilating engineer, Prof. F. S. Lee, professor of physiology in Columbia University, Dr. J. A. Miller of the Bellevue Medical School and Hospital, Prof. E. B. Phelps of the Massachusetts Institute of Technology and later chemist of the U. S. Hygienic Laboratory in Washington, Prof. E. L. Thorndike, professor of psychology in Columbia University, and C.-E. A. Winslow, professor of public health, Yale School of Medicine. Its objects were "to examine and investigate the subject of ventilating systems in the public schools and other public buildings of the state, and the proper installation of the same to the end that a thorough and effective system, which will assure an adequate supply of fresh air, under the best conditions, will be maintained." In his statement in regard to the appointment of the commission Governor Sulzer pointed out that "the problem is far from simple." He continued, "It is much more than an engineering problem, for the best scientific experts have not determined what conditions should be

met by the engineers. Even the most fundamental facts which must lie at the basis of any efforts to ventilate our school buildings, have not been scientifically determined by any experiments which have been made thus far. It is not known, for example, and cannot be known without more adequate experiments than have been possible up to this time, what temperature should be maintained in public school buildings. Indeed, it has not even been proved whether a constant temperature or a varying temperature is more beneficial. We do not know scientifically what degree of humidity should be maintained in our schoolhouse.

"I am informed also that it has not been proved what amount of carbon dioxide in the air is possible before the air becomes detrimental to health. In other words, there is no scientific proof for some of the most fundamental factors involved in the problem of ventilation. On the other hand, I have been assured that if careful scientific studies were made with the express purpose of measuring some of the unknown factors, such studies could be reasonably expected to put us in possession of data which would enable the scientist to tell us with some degree of accuracy what those fundamental conditions are which should be maintained in schoolrooms if they are to be beneficial to the health of children."

The experimental work of the commission began in the summer of 1913 and continued for almost exactly four years. It was completed in the spring of 1917 and the staff, G. T. Palmer,

chief and Joseph Herzstein, secretary, were just beginning the final analysis of the results when war was declared and both commission and staff were immersed in more pressing duties. The data have been at last digested, however, and prepared for publication and the final report of the commission will appear during the coming winter.<sup>1</sup>

The work of the commission dealt with two main problems, first with the physiological question of what constitutes ideal ventilation, and second with the engineering question of how best to secure such an ideal condition in the school room.

The conclusions of the commission in regard to the first problem have been to a considerable extent made public in various preliminary communications and need only be summarized briefly at this time. They were based on extensive experiments, most of which were carried on in two chambers especially equipped by the commission for the purpose in rooms provided in the College of the City of New York by the college authorities.

The main experiments involved a study of the effects of air temperature, air humidity, and fresh and stale air. The temperatures studied were normal temperature 68°, moderately high temperature 75°, and high temperature 86°. The humidities studied were medium, 50 per cent saturation, and high, 80 per cent saturation.

The observations which were made on the subjects by a staff of specialists were extensive in type as well as in number. The physiological obser-

<sup>1</sup>E. P. Dutton Co., New York.

variations included records of changes in body temperature, blood pressure, heart rate, and respiration. In certain special studies, observations were made on the amount of heat produced by the body, the chemical content of respired air, and the air in the lungs, the duration of digestion, and the condition of the blood. An important series of experiments was conducted to determine the effect of air conditions on the appetite.

In addition, studies were made on physical efficiency by means of a stationary bicycle and weight lifting apparatus. Psychological observations were similarly made through exhaustive tests measuring memory, judgment, power of attention, and certain other performances like typewriting, addition, and mental multiplication. Besides the observations mentioned above, a special study was made of the effect of various atmospheric conditions on the membranes lining the nose and throat; and still another series of tests was made on animals to determine the effect of heat and cold on their resistance against infection.

These studies indicated that while both the physical and the chemical characteristics of air may to some degree affect health and efficiency, the physical condition of the air, particularly as it relates to its temperature, is the factor of prime importance in practical ventilation.

Moderate and high temperatures, 75° and 86°, especially when combined with high humidities, tend to interfere with the normal function of heat loss which gives rise to discomfort. A burden is thrown on the heat regulating mechanism with a resulting increase in body temperature, an increase in the rapidity of the heart rate, an increase in the rate of breathing, and a fall in the general tone of the circulatory system. Besides, overheating considerably depresses the ability to perform physical work. Our subjects did about 85 per cent as much physical work under optional conditions at 75° as at 68° and at 86° the work performed fell to 72 per cent. In addition, overheating leads to an abnormal reaction of the membranes of the nose, harming them permanently if long continued. Even after a comparatively short exposure when followed by a chill, it seemingly leads to conditions favorable to bacterial invasion of the air passages. Overheating when followed by a chill also tends to weaken the defensive forces of the body which are brought into play in coping with an invasion of infectious disease organisms, as shown by animal experiments.

The humidity of air, which is another of its physical characteristics, is also of importance in that a high moisture content of the air, especially when the air is warm, militates against heat loss through the evaporation of water from the skin. A high humidity will therefore reinforce the harmful action of a high temperature. On the other hand, low humidities which have been accredited by many with being responsible for all kinds of mischief, were not found to interfere with comfort, nor to induce nervousness or irritability, in a series of careful tests extending over a period of four months. The subjects were girls exposed to relative humidities of 33 and 50 per cent for five days a week, the temperature being 75°.

The chemical conditions of air have been found to exert a secondary effect on the body as compared with the physical conditions. The air of a room without any fresh air supply, containing the odoriferous constituents arising from respiration and from the bodies of the occupants, was found to have no demonstrable effect whatever on comfort, body temperature, rate of the heart, blood pressure, respiration and certain other carefully observed physiological functions. This air contained also large amounts of carbon dioxide. Further, freshness or staleness of air exerted no different effect on mental efficiency, the subjects doing as well in stagnant air as in fresh air.

In but two ways did stale air manifest itself as productive of a real and somewhat immediate effect. As compared with fresh air at the same temperature, vitiated air reduced the performance of physical work by 9 per cent. The second and more important effect was on the appetite for food. The appetite was found to be measurably and definitely decreased as a result of breathing stale air. This effect is not to be minimized in view of the probably significant effect on nutrition which might result from a diminished appetite for food extending over a long period of time.

It is concluded from the experience of other investigations and from the extended researches of the commission that the primary essential for good ventilation is the maintenance of a proper air temperature, of 68° or below, but without the production of chilling drafts. At the same time, there should be an air change sufficient to avoid the accumulation of odoriferous or other substances arising from human occupancy.

The results indicate that in practical ventilation a good air supply and

a room temperature of 68° are desirable. A bounteous air supply in the face of high temperature and overheated air is of less importance and likely to produce more harm than a moderate air temperature of 68° with a less lavish air change.

From the practical standpoint of actual air conditioning in the school-room the following types of ventilation were studied most exhaustively since they were either in actual use or seemed practicable and promising: (Method 1) rooms ventilated entirely through the use of windows; (Method 2) rooms to which fresh air was admitted by windows and from which vitiated air was removed by gravity exhaust ducts; (Method 3) rooms ventilated by means of fans to force air into the rooms, supplemented by a gravity exhaust duct through which air might find its own way out; (Method 4) rooms ventilated by means of fans both for forcing air into the rooms, through special ducts, and for exhausting it from the rooms, the same air being supplied to the room over and over again, after being re-conditioned before recirculation.

The first method, consisting of window ventilation alone without any provision for facilitating ingress or exit of air other than those ordinarily found in a classroom, such as windows, doors, transoms and natural crevices, was found to be unsatisfactory. It gave rise to inadequate aeration, odors, local drafts, and too great a variability of temperature in different parts of the room. It provided comfortable conditions only in mild weather, when liberal use of windows, doors, and transoms was made.

Method 4, involving the use of recirculated air, was studied at the Y. M. C. A. college gymnasium, Springfield, Mass., in certain schools in Minneapolis, and, more exhaustively during 1915 and 1916 in our specially equipped experimental school rooms at School 51, the Bronx. The use of re-circulated air exerted no harmful effects upon either the physiological or the psychological condition of the school children.

From the practical and esthetic side, however, it was observed that the air washing which was necessary in the recirculating system failed to remove odors. On nineteen days, deodorization was attempted by means of ozone. This not only failed to remedy the situation, but made matters worse. The recirculated air was odorous and generally disliked, and gave rise to conditions certainly less attractive than those found in ordi-

narily fan ventilated rooms or in window ventilated rooms of the same building.

While the economic aspect of re-circulating air is conceded, since through its use for some five months in the cold season one-half the fuel expense can be saved, the unsatisfactory atmospheric conditions resulting even from a very carefully controlled system, deter the commission from recommending it as a general practice.

Of all the methods studied, during the early studies of the commission at Springfield, Mass. and in New York City in 1915-1916 the two which most consistently gave satisfactory results were—Method 2, window supply, gravity exhaust; and Method 3, fan supply, gravity exhaust.

The rooms with fan ventilation (Method 3), while well aerated, did not prove as satisfactory as the rooms with window ventilation and gravity exhaust. The window-ventilated rooms seemed fresher and freer from odor and were more comfortable as to temperature. One of the significant findings was that in the window-ventilated rooms the zone of comfort was at a slightly lower temperature than the corresponding zone for the fan-ventilated rooms.

During the following school year, 1916-1917, another four months' study was conducted to probe deeper into the relative merits of window ventilation and fan ventilation, or, in other words, natural versus artificial ventilation. In this investigation, the most extensive and carefully controlled of the practical schoolroom ventilation studies made, fan and window ventilated rooms were compared in several rooms of each of three large school buildings. Three to four schoolrooms of each type of ventilation were selected in each school and detailed observations were made on almost one thousand regular school sessions throughout the morning and afternoon. In addition, more general observations were made on 322 other sessions in other fan ventilated rooms of these same buildings.

In the first of the schools studied, the fan ventilated rooms, as in many earlier studies of the Commission,

In the second school, the conditions in the fan and window rooms were approximately the same as to physical and chemical conditions. The observers' impressions of both types were about the same, pointing to the practicability of effective schoolroom ventilation by means of either windows or fans. However, as tending to favor the window ventilation method, the records of daily votes

show that the teachers registered many more complaints about conditions in the fan rooms than in the window rooms. They liked the air conditions less and found the fan rooms more frequently too warm, or draughty or stuffy.

In the third and last school which was situated in a very congested district in the poorer section of the city, the ventilation in the fan rooms was distinctly superior. The window rooms were frequently too warm, owing to defective control of the radiators by the thermostats. The window rooms were found to be frequently malodorous. The proximity of a stable favored odoriferous conditions in these rooms.

### Window or Fan Method?

The survey indicated that while window ventilation may at times prove unsatisfactory, yet in other instances it compares most favorably with the more elaborate system of fan ventilation, despite the fact that window ventilated rooms have actually a lesser amount of aeration. The general preference which seemed to exist for window rooms appeared to constitute a specific and apparently important difference between the two types of ventilation. The reason for this preference appears to be as follows. Stronger and steadier and more constant currents of air at a higher temperature exist in the fan ventilated rooms; and in order that the cooling effect of the relatively rapid movement of air upon the face shall not produce a sensation of uncomfortable coolness, the air of the room must consequently be maintained at a slightly higher temperature than that maintained in window ventilated rooms where the air flow is less. The walls are somewhat cooler in the window rooms and since active air currents do not here exist to carry off the body heat, the heat loss of the body is more largely effected through radiation. The variable to-and-fro pulsating movement of the air, while not necessarily perceptible as a breeze in the window rooms, seems nevertheless productive of a sensation of comfort, and the lesser air change permits a somewhat cooler air atmosphere to envelop the body without producing a sensation of excessive coolness on the face. This condition is secured, to be sure at the expense of a complete air flushing, but nevertheless with an amount of air change which is sufficient, in general, to remove odors and to ensure really comfortable conditions.

In order to make sure that the gen-

eral preference expressed for window ventilated rooms, both by teachers and by the observers employed by the commission was not based on any preconceptions we conducted a special study in which squads of high school girls were blindfolded and led into rooms ventilated in various ways without any knowledge as to what the actual modes were. Ninety-six subjects were used in all, 24 at a time, each squad serving for one month. After exposure to the air of a given room each girl recorded by a symbol which she could write while blindfolded her sensations as to the atmospheric conditions. In general window-supply, gravity-exhaust rooms (Method 2) and fan-supply gravity-exhaust rooms (Method 3) were compared. We attempted with reasonable success to keep the conditions in both rooms as nearly alike as possible. The average room temperature for both types of rooms for the entire experimental period were only a third of a degree apart. While, however, the temperatures in the middle of the fan rooms and the window rooms were alike, the floor temperature and temperature in the aisles of the window rooms were slightly below those of the corresponding fan rooms. This was due to the greater air flushing in the fan room, which is assured through the use of the fans and which characteristic of fan ventilated rooms makes for a more equable level of temperature throughout the room. The chemical analysis of the air also indicated a superior air flushing of the fan rooms. The de-heating action of the fan room air was greater than that of the window rooms. In other words, the greater air motion of the fan rooms favored body heat loss by tending to displace effectively the layers of air close to the body, to which the body would impart some of its heat.

Turning now to the records of the sensations of comfort of the subjects, in no way influenced by the psychological effect of open or closed windows, light or darkness, favorite locations, the view outdoors, etc., we find that the window ventilated rooms were preferred. They were generally regarded as being more comfortable, and were voted fresher, less odorous, much less stuffy, and less draughty. The window rooms seemed cooler than the fan rooms, apparently because there was a greater difference between the temperature at the floor and at the level of the head when the subject was seated. Although the fan room was more effective in re-

moving body heat, it was obvious that comfort went with coolness, due to lower temperature and less air motion, rather than with air at a higher temperature, having a more rapid movement.

### Effect on School Health

Finally, we conducted during the two winters of 1915-1916 and 1916-1917 an exhaustive study on the effect of school ventilation upon the health of children, a study made possible by the cooperation of the bureau of child hygiene of the New York City department of health. The scope of the study can be indicated by citing the following: The work was carried on for twenty weeks, and involved 5,500 school children in 12 different schools, 58 schoolrooms being studied during February, March, and April, 1916, and 76 schoolrooms during November, December, and January, 1917. Twenty-three nurses gave all their time to the work of following up the children.

Essentially, three types of schoolrooms were compared, namely, rooms ventilated by means of fans with windows closed, rooms ventilated by means of windows and gravity exhaust; and window ventilated rooms, which were maintained at a much lower temperature than was usual, so that actually the effects of three different air conditions were investigated, (a) a cold, (b) a normal window room, and (c) a normal fan room.

The schools were located in various sections of the city, and the race, sex, age, and social make-up of the groups exposed to the various types of ventilation were carefully analyzed to see that no essential differences existed which might unduly influence the results. It might be stated that the children in the fan rooms happened to be the group of somewhat better social status than the others, and also of a presumably healthier race stock. In addition, the fan rooms had relatively least congestion.

The actual ventilating system used in the fan rooms typically exemplified the practice in use in the schools at the time. The window ventilated rooms were not originally equipped for this type of ventilation, and so had to be modified, so that the system of window ventilation did not actually represent the best type of window ventilation which could be devised. In general, however, the comparison could be regarded as one which was very fair.

In securing the records, the nurses visited the rooms under their care in

the morning and afternoon to determine absences and their causes. The homes of all children absent were visited and the exact cause of absence was ascertained. Systematic records were also secured regarding the physical conditions of the rooms. The cold window rooms were kept seven to eight degrees lower in temperature than the normal rooms. The fan ventilated rooms were operated at a temperature two degrees higher than the normal window rooms for the reason stated above that fan ventilation with its high degree of air movement requires a slight elevation of temperature in order to avoid complaint of drafts on the face. The temperature of these normal window rooms was 66° to 67°, that of the fan rooms, 68° to 69°. In one study more marked overheating did occur at times in the window and fan rooms both, while in the second study, overheating did not occur in either type of room. The humidity was approximately the same for all the rooms. The rooms at a normal temperature gave general satisfaction, regardless of the system of ventilation employed, although the fan rooms were regarded as being more often especially fresh and less frequently odoriferous.

### More Absences in Fan Rooms

There were more absences due to respiratory sickness in the fan ventilated rooms, as compared with the other two types of window ventilated rooms. The differences observed were not only found in two successive studies, one confirming the other on this point, but after submitting the figures to a very thorough and critical statistical analysis, it was apparent that the differences in disease rates were really significant. For every 100 absences due to respiratory sickness in the window rooms, there were 118 similar absences in the fan rooms. The most prevalent causes of absence due to respiratory sickness were tonsillitis, colds, and bronchitis.

Strangely enough, even the window rooms which were kept relatively cool, namely at 59°, or about ten degrees cooler than the fan rooms, showed much less absence due to respiratory disease than the fan rooms.

A second significant finding was that among the children present in the classroom, all of whom were examined twice daily by nurses or physicians, there were more children with respiratory affections in the classrooms ventilated by means of fans. Almost two-thirds of these affections were "colds;" one-fifth were

cases of "bronchitis." For every 100 cases of children with such disturbances in the window rooms, there were 170 such cases in the fan ventilated rooms. A striking finding was that among the children present in the cool window rooms, as compared with the normal window rooms, there was no important differences in disease rates.

The most important conclusions from these critical studies, conducted in 216 classrooms of 31 different schools over a period of five school semesters was that window ventilation appeared to be the most promising method for classroom ventilation. While well devised and well controlled systems of fan or artificial ventilation with windows closed were found capable of producing excellent results, it appeared that such rooms ventilated by fans have certain characteristics, inherent in this method of ventilation, which make them definitely inferior to rooms ventilated by a good system of window ventilation, at least when so operated as to produce a high air flow of 30 cubic feet per minute.

Window ventilated rooms have less air change and less air motion, particularly in the zone of occupancy than fan ventilated rooms. This lesser air flushing has, however, been found sufficient to suppress the accumulation of odors. Moreover, this lessened aeration and air flow in window rooms permit the maintenance of a cooler air condition, for which cooler condition a very general preference was found to exist. Furthermore the uniformity of air currents and air temperature characteristic of fan ventilated rooms is probably undesirable. Altogether fan ventilation with a relatively large flow of air at 69° seems to exert a harmful effect on health, promoting susceptibility to disease and affections of the air passages.

### Window System Advantages

In order that the system of window ventilation may be satisfactory there must be ample heat supply through radiators placed below the windows. The heat supply in these radiators must be carefully controlled either by hand or by thermostat. Window boards or deflectors should be used to impart an upward direction to the incoming air. Panes of glass, one foot high, set in the window sash, or a deflector made of parallel curved vanes may be used. There must be openings in the inside wall of the classroom, having at least eight square feet in diameter in all, lead-

ing into air ducts through which the heated air of the room can find its way out. This is the "gravity exhaust duct," which must be provided for successful window ventilation. There is no need of a suction fan in this duct which works against the success of the system. The ducts should have aspirating cowls on the roof and should be provided with dampers to control down-drafts. Without these gravity exhaust ducts, window ventilation is successful only in mild weather when inside doors and transoms are usually also freely opened.

The room must not be overcrowded for over population mitigates against the success of window ventilation. In the average sized classroom, there should be no more than thirty-nine second-grade children or thirty sixth-grade children. There should be a thermometer in the room so that overheating can be avoided. A temperature around 67°F. is most agreeable. Window shades should be so attached as to avoid flapping.

Specifications for a successful system of fan ventilation call not only for adequate provision of fan, motor, duct and register equipment, but also require that the temperature and volume of the air supply in each room shall be mechanically and individually controlled. Gravity exhaust ducts should be supplied as in window ventilation. The incoming air should have a moderately low temperature and there should be no radiators in the room to provide heat. The best arrangement of inlet and outlet is one in which the inlet is placed on an end wall eight feet above the floor level with the outlet on the same wall near the floor. The exhaust duct should be ample in size, should have a damper to control back drafts, and should have an aspirating cowl at its opening on the roof. A thermometer in the room on the teacher's desk should be plainly marked at 70°, above which the temperature should not be permitted to go.

The commission points out that the

nature and environment of the enclosure to be ventilated dictate the method of ventilation to be used, and that what is adequate for one type of building may be inadequate for another. Theaters and auditoriums, for example, must generally rely on fan systems. Window ventilation would prove inadequate for a school which is overcrowded and in a noisy and insanitary district. It is possible that fan ventilation in the schoolroom may be robbed of its disadvantages by decreasing the amount of air supply with a corresponding lowering of temperature, approximating more closely the conditions obtained in window ventilated rooms. In general, however, it seems clear, from the results of the studies here reported, that window ventilation with gravity exhaust will often furnish the ordinary schoolroom with a system of ventilation which is more economical, more comfortable, and more healthful than the ordinary system of forced ventilation.

## Administrator's Part in Hospital Planning

By A. L. BOWEN, FORMER SUPERINTENDENT OF STATE CHARITABLE INSTITUTIONS, DEPARTMENT OF PUBLIC WELFARE, SPRINGFIELD, ILL.

HOSPITAL buildings twenty-five and thirty years ago "just grew." They remain with us today and are occupied because they are too good physically to dismantle but they are very far out of date. When they were planned neither architect or superintendent understood what was needed.

The hospitals built today are, for the most part, the embodiment of the ideas of the architect. Architecture has developed a specialty—that of hospital planning and building. Hospital administration and management have not yet taken the serious part in the development of hospital planning that they should.

The hospital of the future will be the joint product of architect and administrator. Architecture has done its part. It has developed the specialty, as I have indicated, and is studying all the problems it has to deal with. It has even gone into the field of professional management because there has been such a dearth of administrators with a knowledge of what should be incor-

porated in new construction. The architect has given to the modern hospital its exterior style; he has economized on space within; he has shortened distances and installed equipment and devices that are labor-saving. The architect has reached

the limit of his possibilities in hospital construction, unless we are to expect him to qualify as an expert in administration.

The architect has reached

the limit of his possibilities in hospital construction, unless we are to expect him to qualify as an expert in administration.

ture will depend, I believe, upon the hospital administrator. As a profession, hospital management is just emerging from the scene. By cooperation with specialized architecture it can give us a better hospital than any we now have.

The absence of professional hospital knowledge is most clearly apparent in the state and federal service where administration as a profession is an almost unknown quantity. The architect, called upon to plan a new state hospital for mental and nervous cases, for instance, is almost at sea. Even those who have specialized in general hospitals strike a new field and have to guide them only what someone before them has done.

For many years superintendents and boards in charge of these particular institutions have changed so often and have been subjected to such political domination that little knowledge in the planning of new institutions or in developing the old has accumulated. The newest state hospitals are not

Hospital improvements of the fu-

ture will depend, I believe, upon the hospital administrator. As a profession, hospital management is just emerging from the scene. By cooperation with specialized architecture it can give us a better hospital than any we now have.

enough of an improvement, from an architectural standpoint, over the old types to warrant any enthusiasm about them and even less improvement may be noted from an administration standpoint. The congregate institution has been discarded and cottages substituted, but the big unit still remains. An institution of three-story cottages, housing 150 insane patients each, is little better than the old style congregate institution.

I once traveled through nine northern states seeking new buildings at state hospitals or other state eleemosynary institutions. I wanted to get the latest ideas. Illinois was preparing to spend a large sum upon enlargements of old institutions and the erection of a new hospital. My trip was almost fruitless. I found very few superintendents who had given the subject much thought. Even the oldest and most experienced were not builders and left all such subjects to the state architect. They frankly told me they had no improvements to suggest and always left planning entirely to the architect. The result was that gloom and misery were still the prevailing architectural motifs of state hospitals. It could not be otherwise; architects followed what they saw, thinking of course, it was right.

The state architect, as a rule, is a short term political appointee. He wants to do something different from his predecessor. Hence I found on the grounds of these institutions as many architectural strata as there had been political architects since their origin.

Having little or nothing to work on and being determined to do something that none of his predecessors has done, the architect with a com-

mission to plan a building or institution is very likely to be guided by preconceived notions, by what he sees or by a very superficial knowledge gained by a brief experience.

An example will be timely. Such a political architect fell heir to the job of building a new hospital for the insane. Until a few months before he started the task, he had not seen an institution of its character but he soon acquired ideas. Unfortunately his first advisers believed in an institution "all under one roof." Then again he had a lot of notions, hastily conceived out of what he had seen on several trips to state hospitals of the old type.

The congregate hospital is the ideal hospital for the employee. It suits the average superintendent and his staff and everybody else on the payroll. It is easier to manage and handle and requires less thinking. An old superintendent who was trying to operate a cottage institution from his swivel chair was bemoaning the evils of the day which had separated him from the old institution in which he boasted he "could visit any ward in his stocking feet." It was such an adviser who put this architect up to drawing a freak institution, the object of which was to pack as many insane into as small quarters within the shortest distance of headquarters as was architecturally possible and "all under one roof." The gregarious instinct among state hospital administrators subsides slowly.

Final approval of his plans depended upon several men who had modern ideas as to the rights of the inmate himself. After long, heated discussion, they were withdrawn in favor of a strictly cottage institution with plenty of room for recreation and the ordinary activities in which the physical man finds enjoyment, regardless of how seriously he may chance to be afflicted mentally.

Another architect of very much the same type came to me one day with a wonderful discovery. "I don't like the 'T. B.' cottages that have been erected at the state hospitals, and I have de-

vised one that ought to be an improvement. They tell me that the tuberculous ought to have plenty of sunshine, so I have planned a cottage to be made like a green house, —all glass." He was very much disappointed when he heard my objections and realized he could not build greenhouses to house tuberculosis patients.

These men were not to blame. They were sincerely trying to introduce improvements but they had no stock of knowledge from which to derive new ideas. The superintendents recruited from country practice, for political reasons, many of them never before in a state hospital, were not in a position to give advice or tell what these institutions needed. Thus it has happened that thousands of dollars have been wasted and little progress has been made in state hospital building.

A state hospital is overcrowded. The legislature appropriates \$100,000 for a new building. If the superintendent is unable to tell the architect what he wants, how may we expect the architect to know. Often the superintendent has not the faintest notion as to what type of patient the building should be designed to house. It does not occur to him that prevailing styles are enough to drive a man into melancholia. That ward buildings may be homelike and pleasant does not appeal to him. More than once in my experience I have found superintendents who were dumbfounded that I should think their buildings were hideous. Fifty thousand dollars were expended once on one building under such conditions. The architect located it a quarter of a mile from the main and only kitchen and congregate dining room. He provided a dining room in the building, but no kitchen or place where food might be kept warm and no way to get into it with food except through the front door. But he put in a laundry because the building was so far from the institution laundry. While it was designed for men, the plumbing was for women. It was located on the line of a public road traversed by street cars and hundreds of machines daily. The plans did not reveal these incongruities to the superintendent. The architect knowing nothing about the problems of the insane went at it blindly.

Perhaps such things have happened in the planning and erection of general hospitals and for the same reason. It is not my intention to criticize the architect. He has done more than his share. He has tried to de-

The main kitchen of the new Service Building being erected at Alameda County Hospital at San Leandro, Cal., as it looks at the present time. This building is being constructed at a cost of \$125,000 and is expected to be one of the most complete of its kind anywhere.

# Farm Home Care for Insane Patients

BY P. S. WATERS, M.D., ASSISTANT SUPERINTENDENT, ALTON STATE HOSPITAL, ALTON, ILL.

DEALING as we do with abnormal physical and mental conditions in the inmates of our state institutions we are apt, if we are not exceedingly careful, to accept and maintain false standards of living for them. Our greatest obligation to the mentally unbalanced who come to us for care and treatment is to guide them back into a normal relationship to society and it is with this particular idea in view that the following facts are presented concerning the establishment at the Alton State Hospital of what we may term *small group* care of the insane.

Illinois, like many other states, maintains at great expense, large institutions many of which in part at least, have been built according to ideas now obsolete. The care of patients in large groups has a tendency on account of a monotonous and desultory mental life to place them in a groove and hasten deterioration. Patients with persecutory delusions and hyperquantivalent ideas are considerably irritated by conglomerate ward associations so that large group care has a tendency to defeat the very end desired. So far as possible we should strive to individualize our patients more, hence this argument for small group housing.

Farm colonies with their small groups enable us to come into closer contact with the individual in almost natural environment, to study his peculiarities and to remove his difficulties. The writer, after three years of observation and experimentation with this form of care, is convinced that it has a distinct therapeutic value, offering a more hopeful outlook to a larger number of patients than any other form of care introduced in recent years. The farm colony idea, of course, is not a new one. There are farm cottages in all the institutions of Illinois and many other states but almost invariably these are large buildings holding from forty to sixty patients and are viewed as industrial wards for patients concerned in the various activities of the farm. The most important qualification for residence in one of these cottages, as they are usually maintained, is the patient's proficiency as a farm laborer.

A better plan, as we view it, came into vogue at the Alton State Hospital rather accidentally when the thousand-acre hospital farm was taken over by the state and we came

into possession of a number of buildings upon the various tracts of land formerly occupied by the tenants. Comprised in this acreage were two large brick buildings, one large frame dwelling and three small frame structures. The question of utilizing these buildings most profitably confronted us. They were in various states of dilapidation; one had even been condemned and ordered destroyed by state officials. All building for the insane had ceased in Illinois during the period of the war and out of our consequent perplexities at Alton arose the present idea of the farm home care of patients, thanks in a great degree to the ability of Dr. George Zeller, superintendent at that time, to visualize the possibilities that lay in a few scattered farm houses. These farm homes were soon occupied by patients and the work of their repair in which the resident patients assisted was commenced. From these old farm houses four cheerful, sanitary and very livable homes were constructed, housing now about sixty-four of our male patients.

These farm homes for the patients, accommodating from sixteen to eighteen each, neither from their exterior nor interior appearance, advertise the fact that they shelter the insane. Rather they give the appearance of ordinary countryside homes; and within they are filled with the atmosphere of home life. It is this "home and fireside" air that emphasizes the difference of this idea from that of large group care. Every patient added, above this small number of a dozen and one-half, the writer feels will subtract a corresponding amount from the value of the home to the individual.

Of course it may be argued that the farm home is impracticable because it is too expensive to administer with a small number of patients. The cost of the upkeep, in the minds of many, is still a paramount issue, either as a cold business proposition or because of forced economy, the latter condition being the more common. It is only necessary to visit these homes once to see that, so far as the patients' benefit is concerned, they are at least 100 per cent more efficient than the large group wards, and we are able to manage them at no greater per capita expense than the average ward. We place in charge of these homes a man and wife. The latter is charged with

the care of the home while the former is a farm laborer in charge of details. Married couples are much happier employed and remain in the home continuously so only one employee per day is charged to each home. The housewife's work is pleasant and homelike. We always have many waiting for these positions. She trains her cook and household assistants, usually three or four inmates are required for these duties, and gives much time to overseeing the raising of poultry, which is being done on a considerable scale in connection with some of the colonies.

And here, moved by the contrast, the writer would urge the construction of more homelike buildings, as free as possible from the marble and tile and the cold aseptic air so often seen in the construction of our ward buildings. We are not caring for patients accustomed to wealth and luxurious appointments at home.

In times past we have failed in a great measure to consider the value of environment as a remedial agent. There has been too much of the artificial and not enough of the natural. We have been taught to call our inmate a patient and in consequence everywhere about him he sees evidences of the hospital idea; the gowned nurse and white-coated attendant constantly remind him of the fact that he is handicapped. Why not substitute, in place of large impersonal structures for the care of from 30 per cent to 40 per cent of our institutional population, the "home and fireside" idea. Under ordinary conditions these cottages can be built of frame and stucco to hold eighteen or twenty patients for about \$8,000 each. They should house patients engaged in every form of industrial occupation, as well as convalescents and cases where a small group care seems especially indicated.

The patients of our Colony One take care of our horses and some poultry. Colony Two is beautifully situated among large maple trees and overlooking a small lake; no other buildings of the institution are in view except two other colonies. Here we have specialized in the raising of water fowl and from a few pair they have increased to a point where several hundred can be seen any day swimming upon the lake, an invigorating and healthful sight for our patients when they sit upon the porch

after their day's work. Colony Three is a large farm dwelling, the occupants of which are employed in the dairy a short distance away.

Colony Four, most interesting of all, is not essentially an industrial colony, but has been gradually developed as a convalescent and reeducational ward for a few selected chronic cases. It is an assemblage of three small frame dwellings, once located at different points upon the farm and now made into a very cozy little home. Here a number of recoveries have taken place and many patients have gradually improved. Some time ago a baby was born to the mother in charge of this colony and allowed to remain there with its father and mother. This was a fortunate thing for a number of the patients in whom a return of normal interest apparently began with the entrance of the little stranger into this oddly assorted group. One not having seen it can scarcely appreciate what the presence of this child means to the life of this little colony. Relatives of the patients located here rejoice in their good fortune and insist upon their remaining.

One of the members of this group, an artist, who had been in another institution for twenty-five years and most of the time in closed wards, has recovered. A small studio was arranged for him when he produced some quite creditable paintings. The little child, he often remarked, had brought a new interest into his life. He has now been away for the past four months upon parole and is earning a living by his painting. Others of the colony assist with poultry and garden and two work in the carpenter shop. Many others who have been upon the receiving wards for months with little or no improvement have shown a marked gain and even recovery in the quiet, cheerful atmosphere of their rustic home. We regret that space will not permit giving a more detailed report of these cases. The observation of their improvement has been the most gratifying bit of experience the writer has enjoyed during his connection with state institutional work.

#### Advantages of Farm Colony

To watch the progressive, day-by-day awakening of the stupid dementia praecox, who for years has been deteriorating, emphasizes more than words can tell the importance of environment as a therapeutic agent in the treatment of the insane. Occupational therapy, our latest and possibly most powerful reeducational agent,

loses much of its potency because the patient cannot be removed from the mire of his congregated ward environment and into the stimulating atmosphere of rural home life. Let us hope that the day is not far distant when the state will grasp this opportunity and instead of constructing more large buildings will build a farm home type of structure for housing the occupational, industrial, vocational patients and as many of the convalescent, acute cases as can be treated in this manner.

The small group farm colony care of mental cases, then, has the following advantages:

1. It affords a quiet farm home environment.
2. It does away with the irritating effect of conglomerate ward associations.
3. It removes the hospital or mental invalidism atmosphere.
4. It represents economical construction and maintenance.
5. It permits the study of individual traits together with the gradual increase of individual responsibility.

#### The Red Discoloration of Cured Codfish

The occurrence of red discoloration on food stuffs is of extreme antiquity. Outbreaks of bloody food have often been attributed to *B. prodigiosus*. Harrison and Kennedy (*Tr. Royal Soc. Canada*, 3 S., 1922, vol. xvi) report the isolation of a new microorganism responsible for the red discoloration of codfish and serious economic loss to the fishing industry. It is impossible to classify this organism in any existing genus recognized in the standard classification. If a new genus is warranted it might be called *Erythrobacter*, but for the present the discoveries propose the name *Pseudomonas salinaria*. The immediate source of the contamination is the solar salt used for curing the fish and the ultimate habitat appears, from examinations of the brine from salt works, to be in the semi-tropical waters from which the salt is obtained by evaporation. The organism exhibits extreme pleomorphism and shows optimum growth in a salt concentration of 16 per cent; it is difficult to stain, does not grow on ordinary laboratory media, and is nonpathogenic. The discoloration produced on the surface of the dried fish destroys its market value and since solar salt seems preferable to mine salt for the curing of fish, the writers propose kiln drying of the salt

at 100 degrees Centigrade, a temperature above the dry heat thermal death point found in the laboratory investigations. The salt producers claim that storage is sufficient but studies on the oldest samples obtainable did not substantiate this contention.

#### Standard Methods for the Analysis of Milk

In the report of the referees—Robert S. Breed and R. E. Doolittle—for the bacteriological and chemical analysis of milk, presented at the recent meeting of the A. P. H. A., it was recommended that the methylene blue reduction test be included in the fourth edition of the Standard Methods for Milk Examination as a provisional method; that the ratio between the official plate count and the count of individual bacteria by direct microscopic examination be placed at 1:4 instead of 1:5 as in the present report.

It was also recommended that the chemical methods of the Association of Official Agricultural Chemists be adopted as the standard methods of the American Public Health Association and incorporated in the fourth edition of the Standard Methods for the Examination of Milk.

These recommendations were adopted and referred to the Committee on Standard Methods with power to act in editing and publishing the new report.

#### Indiscriminate Tonsillectomy Condemned

Believing that the tonsils, like all other lymph nodes, exercise a protective function, Hieman (*Am. J. Dis. Child.*, Sept., 1922) condemns the indiscriminate removal of tonsils. He states that tonsillitis is usually only a manifestation of systemic infection. If the infection becomes more generalized, it manifests itself in spite of the tonsil, not because of it. In rare instances, however, the tonsils may cease to function and become clogged filters, in which case they may prove a source of infection, but this condition should be proved before they are sacrificed.

In order to alleviate the part-time physical training program necessitated in New York high schools by over-crowding, George J. Ryan, president of the city board of education, is attempting to gain permission to use the public parks and armories for this purpose.

# Jewish Free Hospital for Consumptives

THERE has been a tendency in recent years to emphasize the proper care of the tuberculous at home—to impress upon people that nourishing food, proper rest, and fresh air, main instruments in the fight against tuberculosis, can be secured in any climate and that there is no need for the patient to spend all his funds in the search for climate. The “get cured at home” idea has been disseminated to stop the migration of persons with insufficient funds to climates where, friendless, they often suffer from lack of care. Important as food, rest, and fresh air are in the treatment of tuberculosis, however, experts have long recognized the value of a high dry climate in alleviating the symptoms and effecting a cure.

Mountain air, because of its dryness, its altitude, its freedom from dust and its great amount of sunshine, has been accorded the ideal climate for the tuberculous. Its physiological effect is exhilarating to the healthy person as well as to the sick. The barometric pressure is low in proportion to the height above sea level and the partial pressure of oxygen is correspondingly diminished. The physiological result is deeper breathing. The tenuity of the atmosphere combined with brighter light leads also to an enrichment of the blood so that a greater amount of hemoglobin is in circulation and a larger number of red corpuscles carry it. At a height of five thousand feet, the increase may amount to from 20 to 30 per cent. Experiments have shown

that the total amount of blood and even the number of lymphocytes is increased. Mountain air increases metabolism; it stimulates the appetite.

It is, therefore, with scientific evidence of the positive benefits of high altitude that founders of tuberculosis sanatoriums have sought the mountains for building sites, and Denver situated one mile above sea level fulfills the climatic conditions most favorable to the arresting of tuberculosis. Among the hospitals for the tuberculous in this city is the National Jewish Hospital for Consumptives, the first free hospital for the tuberculous in the United States. “None can pay who enter” and “none may enter who can pay” set forth the policy of the institution whose doors are open to all the indigent sick.

From one small building the plant has grown to twelve including an administration building, woman's building, two buildings for men, industrial school building, dining room and kitchen building, laundry and boiler house, superintendent's house, children's pavilion, and home for nurses.

During its existence the hospital has treated 4,200 patients, has restored 2,421 to economic independence, has improved the condition of 3,077, and has made comfortable 1,123 incurables. The past year it admitted 215 patients, 134 men, 46 women, and 35 children. Of this number 199 were discharged, 85 of whom were restored to health and full earning power; the condition of 63 was improved; the remaining number were advanced

cases when they came to the hospital.

The Grabfelder Medical and Administration building houses the offices, reception rooms, nose and throat rooms, dental department, examination rooms, and the research department. In the Joseph E. Shoenberg Memorial Industrial School building are conducted various classes for men, women, and children, among which are classes in Americanization and citizenship.

Notable research has been carried on in the laboratories of the hospital under the direction of Dr. Corper who has attempted to discover a cure for the disease by chemical means. He has observed that 3 per cent of carbon dioxide causes some inhibition of the growth of the tubercle bacillus in the test tube, and that 15 per cent is tuberculocidal. The American Medical Association *Journal* in explaining Corper's theory says:

Tubercle bacilli will not grow in a carbon dioxide free atmosphere. Cultures of tubercle bacilli buried in the tissues of animals and permitted to acquire the carbon dioxide concentration of the body are definitely inhibited in their growth, while other cultures similarly buried, except that ingress of atmospheric air is permitted, show no inhibition. When viable tubercle bacilli are placed in a closed system, their growth becomes inhibited as the carbon dioxide which the organisms elaborate approaches a concentration of approximately 5.5 per cent., at which concentration respiration of these micro-organisms is also reduced to a minimum. In a closed system the end-products of metabolism automatically inhibit the growth of the organisms that give rise to them.

As a concentration of carbon dioxide, namely, 5.5 per cent, sufficient to inhibit the growth of the tubercle bacillus definitely may occur under normal conditions in the body, it is perhaps not too visionary to assume that this product of metabolism may be of no little importance in relation to tuberculosis. It has been said that this finding reopens the consideration of the influence of fatigue, exhaustion, exposure, metabolic diseases, etc., as probable etiologic factors in the causation of tuberculosis in view of their ability to alter the carbon dioxide content of the body. Experience warns us against undue enthusiasm or false steps in a field in which so many hopes of scientific progress have been shattered in the past generation. Nevertheless, all new findings, as those gained by Corper, deserve a respectful consideration.

The physical plant of the hospital has kept step with the development of research. All the buildings have been modernized with outdoor sleeping afforded to all patients. The aim of

Woman's building of the National Jewish Hospital showing how an old building was made to fit the demands of open air tuberculosis treatment.

the institution is to give to the patient within its walls all the comforts and the care that the wealthy person receives.

## Delaware's New Schools

REALIZING that the cause of public education was failing of state support, the Service Citizens of Delaware through their school auxiliary association decided to use the Pierre S. du Pont educational fund of \$3,500,000 for the building of rural schools to replace old and ramshackle ones that had been in use for years. One million of the fund set aside for the building of schools for the negroes was available at once. The \$2,500,000 appropriation for the building of white schools, however, was not available immediately and action therefore has been somewhat delayed.

The aim of the organization has been to supplement and assist and never to duplicate or usurp the functions of the state officials, states Joseph H. Odell, director. During the past year the Service Citizens have built 18 schools for white children, and have built a kitchen and addition to dining room and two dormitories for the Woman's college, making a total of 93 rooms, with pupil capacity of 2,644 at a cost of \$644,202.40. Thirty-six schools for negro children numbering 47 rooms and accommodating 1,950 children were built at a total cost of \$295,500.

Fifteen schools for colored children remain for future construction and building will begin as sites are secured. The buildings are modern and complete in every detail and are constructed for a maximum of use as well as beauty.

But with the building of these

schools it became a question as to how many children were taking advantage of the increased facilities. Investigation showed a low school attendance. The Citizens Service therefore appointed a committee to study school attendance and the reasons for absence, and an endeavor was made to bring the children back to school.

To provide medical inspection and dental hygiene in the public schools the following organizations have united with the state board of educa-

tion—child welfare commission, Delaware chapter of the Red Cross, Delaware Medical Society, Delaware Dental Society, the Service Citizens, and the Delaware School Auxiliary Association. The work was financed by these organizations and was used as a demonstration to the state to show them the need for such service. Dr. William J. French, director of the Child Welfare Commission, was adopted by the state department of public instruction as its director of medical inspection and had charge of the work. Under Dr. French's direction 11,867 school children were examined with the finding that 894 were free from defects, and that 3,419 were 10 per cent or more underweight.

Dental work has been supervised by members of the committee representing the State Dental Society, the actual work being done by two hygienists whose duties consist mainly of examination, cleaning of teeth, prophylactic treatments, and talks and demonstrations. Those who need other dental work and can afford to pay are referred to private dentists while others are taken care of by the committee. Up to April 8 of this year the Dental Unit had examined 1,314 children, with a finding of 1,228 defects. Corrective work was performed for 176 of these, and 86 were found to have perfect mouths. Only 10 children have refused examination.

Dr. Frankwood E. Williams has been appointed medical director National Committee for Mental Hygiene to succeed Dr. Thomas W. Salmon.

The old negro school at Bridgeville is typical of the ramshackle buildings replaced by modern structures by the School Auxiliary Association of the Service Citizens of Delaware.

*Agencies in 305 other cities*

*Man—your first pair of Cantilever Shoes will bring back the old time spring to your step and give your feet a new lease on life*

Comfortable feet never interrupt a busy mind. Active men who need their heads to think with and their feet to walk on, are quick to appreciate the comfort of Cantilever Shoes.

Cantilever Shoes are made with consideration for the necessary functions of your feet, as well as for their natural shape. They have flexible arches, like the arches of your feet, that permit the foot muscles to exercise and grow stronger.

Some men do not realize that the feet should be free to exercise just like the arms and legs. Feet that are held rigid in ordinary shoes are losing their muscular strength. Weak foot muscles cause weak feet. The weakened muscles are not able to hold the 26 small bones of each foot in their proper arched positions. The Cantilever Shoe has a snug-fitting shank which supports the arch naturally and without appliances. It gives your foot muscles freedom to exercise.

Cantilever Shoes have a natural sole line that gives the toes plenty of room. The heels are slightly higher on the inside to help the feet assume a straightforward position. This distributes the body weight more evenly over the foot and takes the strain off the inner arch. In Cantilevers you will walk with ease and snap. Your circulation will be better, your health will be benefited and you will feel your feet speed up.

You will like the looks of Cantilevers. They are made of fine leathers on good lines, and are reasonably priced.

Cantilever Shoes are sold in practically every city. If no dealer listed at the left is near you, write the manufacturers, Morse & Burt Co., 15 Carlton Ave., Brooklyn, N. Y.

*for Men and Women*

velop a specialty but he can go only so far.

The point I desire to make is this; the plans for a hospital, public, general, state or federal, should be roughly drawn by an expert hospital administrator who is competent by study and experience to tell the architect exactly what he wants, what he desires to accomplish and how he expects to accomplish it. The architect's business is then plainly marked out. He should draw the plans as directed. He must fit the building to the site and design it within the funds available. He should know how to do what the administrator wants done

and should be free to advise and suggest, even though he contributes nothing thereby. The direction should emanate from the administrator to the architect and not from the architect to the administrator. And in case of dispute, the administrator, if he knows his business, should be trusted to make the decision.

#### Needs Vision of Future

An industrial or commercial corporation desiring to expand its plant knows exactly what is needed,—a building of certain dimensions and height to take care of a certain production. The architect gets his in-

structions from the corporation and carries them out. It should be thus in the hospital world. No conflict between architect and builder is involved or implied. The architect retains his important and essential position. With the aid he should get from the expert administrator he would make a few mistakes. I believe the crux of the whole subject of better hospitals is the professionalized administrator who understands hospital problems, who has a practical appreciation of what such institutions have been created to do and who has vision and imagination to see the possibilities and demands far ahead.

## The County Jail a Passing Institution

### Chicago Survey Reports Against the Traditional Type of Jail

BY FRANK D. LOOMIS, SECRETARY, CHICAGO COMMUNITY TRUST, CHICAGO, ILL.

FOR many years there has been agitation for a new jail in Cook County. There has been agitation for new jails for many years in many counties. The difficulty is that when the new jail is built it soon proves to be about as bad as the old one—so the agitation for a new jail begins all over again. Jails as a rule are not condemned because they are worn out. They are condemned because they are overcrowded and filthy. The public is made to believe that these conditions will be corrected if the County is allowed to build a larger jail. Hence the agitation.

That has been the experience in Cook County. Our present "new jail," built of solid steel and stone construction in 1895, was scarcely completed before it was condemned. By 1910, both the "old" and "new jails," operated as one unit, had become as crowded as the old one had been before the new one was built "to relieve the over crowding," and the International Prison Congress, meeting here in that year, condemned the whole structure as one of the worst jails to be found anywhere.

Since 1914, four different proposals for bond issues for a new jail have been submitted to the voters. Each proposal has been defeated. There was a widespread feeling, developed under the leadership of some of our large civic organizations, that a new deal was needed—that it would be a useless waste of money and of human material to go on indefinitely under the old policy of building ever

larger jails to be promptly filled up as soon as the new space was available. After the failure of the fourth bond issue proposal in the Spring of 1921, the Board of County Commissioners decided to ask the Chicago Community Trust to make a survey of the whole situation and present recommendations which might lead to permanent improvements.

The Community Trust is a charitable foundation which receives gifts in trust and uses the income for philanthropic purposes. It maintains a bureau of surveys and exhibits and has conducted a number of social studies. We were fortunate in being able to secure as the director of this survey, Mr. George W. Kirchwey, LL.D., for many years Dean of the Columbia University Law School; warden, for a time, of Sing Sing Prison, New York, and an internationally known criminologist. He had as his immediate assistants Mr. Winthrop D. Lane of New York, and Mrs. Kenneth F. Rich of Chicago. Work was begun early in February, 1922, and was completed in July.

#### Jail Population Suffers

It will not be necessary to review here at any length the conditions which were found in the Cook County jail. They are much the same as conditions in other jails in the United States, except that our jail is somewhat larger than the average and is

possibly more over-crowded. "Taking the country over," says Dr. Kirchwey in the introduction to the report, "the County Jail is the least human of all our American institutions."

The "old jail" in Cook County, erected in 1874, had individual cells for 136 persons; the "new jail" added 180 cells; making the total normal capacity of the combined institution 316. But the jail population in 1921, reached the maximum of 1,013 inmates in a single day. There were ten days when the population was 1,000 and upwards; and only six days in the year when it fell below 700. For a large part of the year many of the cells had to be occupied by five men. Three and four in a cell is common. The cells are about ten feet long, five feet wide and seven and a half feet high. The bunks take up half this space. The cells are dimly lighted and poorly ventilated. The men, and the boys, must spend twenty hours of each day there. Four hours they have for "exercise" in the "bull-pens"—artificially lighted enclosures surrounded by the tiers of cells.

The kind of people who fill the jail and the length of time they stay there are probably about the same as in most jails. It was found that 21 per cent of the 10,642 people who were confined in the Cook County jail last year were boys twenty years of age and under. The largest group, 41 per cent, were young men between the ages of 21 and 30. An individual history study of 101 cases, selected at random, showed that 86 per cent

1. Copies of the complete "Survey" will be mailed to interested individuals upon receipt of request and ten cents postage by The Chicago Community Trust, 10 S. La Salle St., Chicago.

## Weak Arch and Flatfoot —

that need mechanical correction are very prevalent and frequently are associated with painful heel, callouses on sole, fatigue, nervousness, neurasthenia, physical exhaustion and rheumatic tendencies. Heavy people and those who are constantly on their feet and whose occupation requires them to assume a posture conducive to the weakening of the leg and foot muscles are usually victims of these complaints. The corrective treatment is simple. Remove predisposing causes such as short hosiery, improperly fitted or constructed shoes and have patient fitted to

### *Dr Scholl's* *Corrective Foot Appliances*

which are scientifically constructed to relieve muscular and ligamentous strain, remove abnormal pressure and restore foot to usefulness. There are distinct types of appliances for each condition. All quickly and easily adjusted to any degree of elevation or curvature, assuring the physician dependable results.

Leading shoe dealers and surgical supply houses in every locality carry Dr. Scholl's Appliances and have also been instructed in Anatomy of the Foot and the proper method of adjusting the appliances to fit both foot and shoe.

Chicago

New York Toronto London, Eng.

had been resident in the county for at least a year; 70 per cent had local school records; the work record, from local places of employment, was found to be available in 92 per cent of the cases; 94 per cent were attached to families living in Chicago, or were known to neighbors. Study of these records revealed that early education in nearly all cases had been meager; 20 per cent are described as "well-disposed but incompetent;" but the proportion of workers to "loafers" was not less than 81 to 19.

Fifty-nine per cent of all the inmates of the jail in 1921 claimed never to have been arrested before; and 25 per cent were second offenders. Study of jail records for a number of years indicated that at least a third of all those committed to the jail will eventually be released. A small proportion of these will be released on refusal of the Grand Jury to indict; a very considerable proportion, often more than one-half of the entire number released, will be discharged without trial; and of all those finally brought to trial, probably more than 10 per cent will be acquitted.

As illustrating the length of time persons are held in the jail, it is reported concerning cases held on December 1, 1920, that of 85 dismissed without being brought to trial, only ten were confined less than a month; only 24 less than two months; forty, or 47 per cent, were in jail over 100 days; and 23, or 27 per cent, from 150 to 300 days. Of 56 brought to trial and acquitted, only two were confined less than a month and only fourteen less than two months. Of 404 brought to trial and convicted, only ten were held less than a month and only 80 less than two months. Fifty per cent were confined over 100 days; 30 per cent over 150 days; 20 per cent over 200 days; and 13 per cent over 300 days. Fifteen individuals were held more than 400 days. Thus it appears that, whether innocent or guilty, the average individual committed to the jail and unable to secure bail will spend three or four months there.

In the Cook County jail as in most jails in this country, there is little provision for classification or segregation of inmates. First-offenders are confined with hardened criminals; boys are placed in cells with men; the degenerate and the unsophisticated live together; the sick and the healthy, the clean and the filthy, the dope-fiend and the discouraged young man are all herded together indiscriminately.

The most dangerous criminal in the lot is the hero of the "bull-pen." Thus our jails become schools of vice. Boys and girls, men and women are better when they go in than when they come out.

This charge has been made so often and by so many people that it ceases to be effective. Is it not a startling thing that large institutions, maintained by local governments at great expense to the tax-payers, having as their professed object the reduction of crime, have become instruments of crime—agencies through which the volume of crime and degeneracy are actually increased—institutions so productive of vice that it is said that there is no other single institution in the average American community, public or private, which does so much harm?

It has been often said that the only remedy for the county jail is no jail. This does not mean that there shall be no way of holding persons accused of crime until they can be tried. It means that we need a new system, and that is the recommendation of the Cook County survey. The Survey recommends that the name "Jail" be abolished and that there be established in its place an institution to be known as the "Central House of Detention?" The very change in name implies a wholly different character of institution, and it is doubtful if the character of the institution can be changed without a change of name. The terms "jail" and "jail-bird" are inseparably associated in the public mind—the one implies the other.

A House of Detention should be used for purposes of detention only. Persons convicted of crime should be promptly sent to the proper penal institutions. A House of Detention should be a *house*, with rooms, not cells; with windows and light and air; with ground outside, and possibilities for useful work and wholesome recreation; there should be opportunity for education and moral improvement of the inmates. "It is here that opportunity presents itself for the last time perhaps, to turn back this tide of human derelicts in the ways of decent and honorable living."

If the size of the population in the house of detention increases, a new house in the same enclosure can easily be built. Each house should be of simple and relatively inexpensive type of construction. Provision for numbers of inmates in different houses can be expanded or contracted without great difficulty. A relatively few cells only may be provided for indi-

viduals who prove untractable or dangerous.

The traditional type of jail permits none of these things. Its monumental character is fixed in steel and stone which cannot be changed. It is extravagant—it must be built large enough to provide for all possible expansions throughout the life of a building of such a character—such a building, costing in our larger cities many millions of dollars, ought to last a hundred years or more. When its single cells are full, two or more prisoners must be confined in one cell; if any cells are empty, the law's delays are made convenient—the cells will soon be occupied.

Another element bearing upon the type of institution to be built and urged by the Survey as a reason for the temporary type, is the fact that the conceptions and methods of treatment of prisoners are undergoing rapid changes. These changes are certain to affect both the size and character of the institutions to be needed. May we not hope for greater efficiency on the part of the police, which will reduce the present large numbers of persons needlessly arrested? Will there not be improvements in the bail-bond system and extensions of the principle of probation so that many poor but reliable persons now held in the jail may be released on bond or on their own recognizance? Will there not be reforms in the administration of criminal justice so that the period of time awaiting trial will be greatly reduced? Is there not likely to be a growing sentiment in favor of allowing those who must be held in public institutions awaiting trial to do useful work which will support themselves and even help to support their families? A large, monumental type of structure would not permit these changes and one of two things would happen—the reform would be thwarted or the building would be relegated largely to disuse. In view of these considerations, the Survey unqualifiedly recommends the temporary type of institution.

The Survey makes two other major recommendations which are in harmony with the central recommendation. It recommends that there be a separate detention house for women, entirely distinct from the main institution, in which all women now held at the various police stations as well as at the jail, shall be held while awaiting disposal of their cases in Police or Criminal Courts. It recommends that there be a separate detention house for boys between the ages of 17 and 20, inclusive.

# KOTEX

## At stores and shops that cater to women

**K**OTEX, the new sanitary pads, are made from Cellucotton, that wonderful war-discovered absorbent dressing. Since peace released Cellucotton to universal service, the best hospitals are using it wherever a cool, efficient, absorbent surgical covering is required.

Kotex are made of thirty-six layers of Cellucotton absorbent, 3½ inches wide by 9 inches long, enclosed in fine gauze 22 inches long, which allows generous tabs for pinning. They are good enough to form a new sanitary habit and cheap enough to throw away.

Cellucotton Products Co., 166 W. Jackson Boul., Chicago  
51 Chambers Street, New York    ::    Factories: Neenah, Wis.

*Regular Size, 12 for 60c*  
*Hospital Size, 6 for 45c*

Sample of either size free on request.

Kotex vending machines are being installed in women's rest rooms everywhere — hotels, office buildings, restaurants, theatres and other places from which may be obtained one Kotex with two safety pins, for 10 cents.

## The Chance of the Child Who Does Not Hear\*

THE general effectiveness of any individual depends upon the body of his experience. The different channels through which the average individual is able to register his experience are sufficiently varied to afford him a fairly adequate account of his physical world. Sight, hearing, the sense of smell and taste, tactile and muscle sense, including pressure, heat and cold, and the complex sense of equilibrium, tend to make the world of the individual seem stable and his sense of things complete. Adaptability, and contentment as a harmonious response of the whole organism to its environment, may under such conditions develop normally, uninterruptedly, and without undue strain on psychic functions.

A severe strain, however, is placed upon mentality and disposition with the loss of a single function—a readjustment of the whole mental organism is necessary. With the loss of vision, for instance, the personality must learn to deal with a colorless, formless mental content and mental imagery must find what substitute symbols it is able to create for itself in order to achieve expression.

Reorganization is still more complete in the case of the deaf. Hubbard<sup>1</sup> gives an interesting account of the reassignments of functions with the loss of hearing. New service is exacted from all the faculties, accomplishments are forced and latent talents developed. The degree of sense-reinforcement possible in visual loss, however, greatly exceeds the compensations possible in the case of deafness, for hearing is very intimately related to the emotional centers. The refinements of meaning carried by inflections of the voice are all lost. Literal meanings of word forms replace the flexible modifications in meaning that cannot be construed by the deaf. "They miss the vitamins of the daily mental pabulum" says Hubbard.

The loss of music does not affect all to the same degree, for about half of us are tone deaf naturally—meaning that about half of us are not susceptible to the thrills of refined music. But emotions are a natural outlet for suppressed feelings,

and deafness seals this flood gate. This is not to say that the deaf cannot find expression. It only serves to indicate the extra strain this handicap puts upon the development of personality. The deaf are required thereby to make an intense study of facial expression to find a suggestion of the sentiment conveyed to the rest of us by modulation as well as by the meaning of the sentence. "They study not the lips alone but the whole face, mouth, eyes, eye-brows, even wrinkles and dimples, head poise and gestures, keenly searching for sentiment, and they do succeed in a marvelous way. They become expert judges of character from that sort of practice." This sort of training develops in the deaf character and a penetrating mind, but a satisfactory and cheerful adjustment is delayed by this handicap and, under unfavorable conditions, may become impossible. Cheerfulness on the part of the deaf is the visible evidence of winning the game in spite of handicap.

Knight Dunlap<sup>2</sup> discusses interestingly the psychic differences entailed by variations in auditory acuity. People are usually classified either as deaf, or hard of hearing without especial regard to the peculiarities involved in defective hearing. Per-

2. Dunlap, Knight: *The elements of scientific psychology*. C. V. Mosby Co., St. Louis, 1922.

sons suffering from reduced sensitivity to high pitches, may be "normal" up to one thousand vibrations per second, and may be even hypersensitive to tones in the lower part of the usual range; yet they have difficulty in understanding words, and especially whispering, because the discriminating between consonants depends upon the hearing of the high overtones in the vocal sounds. Apparent dullness of children in school is sometimes due to this cause, and inability to understand whispers easily is always a sufficient reason for having the hearing tested by a psychologist. This condition is not detected by the average tests employed by ear specialists. Not being subject to therapeutic methods, these conditions have not commanded the attention of physicians or the makers of audition tests.

These cases are not helped by the microphone devices, now much used by deaf people, because these devices intensify the low pitched tones relatively more than the high pitched, and so increase the difficulty of hearing language. In another type of deafness, in which the reduced sensitivity extends also to low pitches, these devices are beneficial. A third type of deafness, characterized by reduced sensitivity for low pitched tones, with less or more for the higher pitches, might be supposed to exist, on the basis of some theories of

Teaching vocalization through the sense of touch. The natural rhythm through which relations are observed and recorded by the normal child are lost upon the deaf. New avenues for the reception of stimuli must, therefore, be created. Meanwhile intense study of facial expression is made to find a suggestion of the sentiment conveyed by modulation as well as by the meaning of the sentence.

audition, but no such type has come under observation.

The scientific help for the deaf, therefore, involves psychologic diagnosis, and educational methods which capitalize as far as may be the residual hearing as a basis for organized sense-impressions. A valuable supplementary help is in organizations for the deaf making it their object to break the isolation enforced by their handicap, but that is another story. Statistics were reported in 1921 on sixty-eight schools for the deaf, with 11,316 pupils enrolled; in addition to this number there were 69 public schools handling 2,482 pupils, and seventeen private schools with a registration of 605, in all a very inadequate provision for those who are defective in hearing if the percentages on the basis of recent tests are accepted. The highly constructive work being done by the Detroit Day School for the Deaf is described by Gertrude Van Adestine<sup>3</sup>, principal.

The Detroit Day School for the Deaf was organized in its present form in September, of 1900, and is a part of the general plan for the education of the handicapped child. It is supported by the state and the city of Detroit, and is open to pupils who by reason of defective hearing cannot make satisfactory progress in the regular grades. The pupils are taught speech and lip reading and with a few exceptions follow the course of instruction planned for hearing pupils. The ages of pupils vary from three and one-half to eighteen years. They are admitted at such early age because it is very important that the voice be trained and good speech habits

3. Van Adestine, Gertrude. What Detroit is doing for Children with Defective Hearing. *City Health*, September, 1922.

formed while the child is still young. Lip reading is also taught, as a means of understanding the speech of others. Much is done in developing rhythmic appreciation through the sense of touch, by means of work with the piano.

The physical defect of deafness is not in itself visible, and its presence is noted only by its results, or the failure to follow spoken direction. Too often the child is classified as stubborn or inattentive, when he merely fails to hear or hears indistinctly what is said to him.

Cases of defective hearing may be divided into two general groups—the totally deaf, and the hard of hearing. The case of the totally deaf child offers no confusion as to classification. This type is easily recognized and he is at once placed in his own special group in the School for Deaf. The classification of the hard of hearing child is more complex, and there are conflicting opinions as to the degree of handicap which makes it necessary to send the pupil to the deaf school.

Of the number of hard of hearing children who have been transferred from the regular grades, are the following types:

(1) Children with defective hearing who are failures in the hearing schools and are sent to the deaf school as a last resort, these children having lost from one to four years in mental development that their school experience should have given them. Their hearing is deteriorating. They are tired of listening and not hearing what is said to them. They become absentminded, distraught and are often troublesome cases so far as attendance and discipline are concerned. They are the type of children who must have the faculties of

the mind reorganized before they can concentrate on any subject. They need constant supervision and direction in all class room work in addition to special work in lip reading by a trained teacher of the deaf.

(2) The children who still have hearing through which they may gain the major part of their instruction, but whose hearing is becoming defective. The mental development has not been retarded by failure to hear and the physical condition has not yet been disturbed by the nervous strain of continually listening without success. This is the only type of deaf child who could with profit attempt to work again in the grades with hearing children after lip reading has quickened his comprehension.

It is important that pupils who exhibit any degree of hearing defect receive attention immediately the defect is discovered, to prevent the development of character defects. These may be classified as, (a) defective speech (sometimes almost unintelligible), (b) growing dislike of school and lack of interest in school affairs, (c) an increasing sense of failure and a lack of any sense of responsibility.

"One or more of these conditions are present in most cases of pupils received in the department," states Miss Van Adestine. "However, with our small classes and individual attention we are able to help the pupil regain his self-confidence and the desire for self-direction. We must have sufficient time to effect this desired improvement before the pupil is allowed to leave our department, since the accumulated shortages arising from several years of neglect cannot be made up by a short period of training in lip reading. A recent survey of our pupils indicated many different physical conditions of the ear, and consequently a wide variation of different degrees of hearing. For purposes of further study we have classified the different degrees of hearing into such groups as will indicate educational possibilities. Six groups were found to cover the field in a general way. They are: (1) Totally deaf; no sound perception; (2) conscious of sound, but cannot imitate; (3) imitative sound perception; (4) imitative speech; repeats words and short sentences; (5) hears (comprehends) conversational speech at — feet; (6) apparently normal hearing but does not speak. These lines between these groups are not sharply drawn, and pupils may pass from one group to the next, depending, however, on the cause of deafness and the condition of the ear.

Children learning the rhythm of music through the sense of touch.

# “ELIMINATION OF WASTE

*is definitely increased by  
the ingestion of raw yeast”*

A double series of tests, recently conducted to determine the laxative effect of Yeast, has revealed some surprising facts.

The subjects were isolated over a period of weeks, and fed according to a rigidly regulated scheme of diet. Examination of the bulk, moisture, and chemical constituents of the feces was made from day to day. The findings showed that adding Fleischmann's Yeast to the diet in quantity of two to three cakes per day produced the following results:

A definite increase in the elimination of waste by the bowel.

Increase both in the bulk of the feces and in their moisture content.

A laxative effect more marked with the ordinarily constipated

subjects than with the normal ones—indicating that yeast acts as a bowel regulator rather than a cathartic.

Further research work on both animal and human subjects is now under way. The Fleischmann Company is sponsoring these important investigations, and is anxious to give the full results to the medical profession as soon as possible after they are complete.

City ..... State.....

More than fifty per cent of our enrollment fell under groups one and two; 25 per cent fell under group five."

The above scale for the classification of different degrees of hearing as developed in the Detroit school has been accepted by the state department of public instruction as the classification to be placed on the official annual reports of the Day School for the Deaf.

For some time the Detroit Deaf School has been doing such research work as will lead to remedial measures for the deaf. Special stress has been placed upon auricular training which is given for the following reasons: To give the pupil the stimulus of sound sensation; to improve his

voice and language concept; and to stimulate and aid in retaining the residual hearing.

At the present time investigation of children in the city schools and the careful measurement of the hearing have not reached the point where the number of cases of hearing defects and how they should be classified can be stated with assurance.

Figures from the Board of Health statistics indicate more than seven hundred cases of ear defects reported by school physicians from the examinations of about 40,000 pupils in three groups—the first grade, the fifth grade, and the underweight group. It is planned to make a further study of these groups, and a report of the finding will be available later in the

year on which to base future activities.

All cases of defective hearing are reported to the clinical department of the board of education. Here the pupil is referred to an ear specialist who returns a statement of the diagnosis together with a recommendation for medical treatment and educational training. An aurist has recently been specially assigned to this department by the board of health and Dr. Emil Amberg will hereafter supply the much desired medical cooperation.

With these increased facilities and the new School for the Deaf, recently allowed by the council, every child in Detroit whose hearing is defective may have the special training in lip reading and the benefit of auricular training at an early age.

## School Health Work Extends to the Community

THE school affords an ideal means for the spread of contagion.

Here representatives from every section of the community are brought together in an atmosphere that is prone to be overheated and otherwise vitiated, and are held in close quarters over periods varying from four to six hours daily. The greater percentage of the contacts are children who have not acquired those conscious habits of personal hygiene which, when all is said, must be considered the best ultimate protection of the individual against contagious disease. Hence everywhere the opening of school witnesses the speedy development of sporadic cases into definite foci of infection.

In the case of Milwaukee just prior to the school year of 1922-23 a few cases of measles were known to exist among several south side families of foreign extraction. Visiting back and forth accounted for a second area just across the river, the disease be-

ing still confined to definitely circumscribed areas. The first week of school 10 cases were reported; 13 new cases were discovered the second week; 19 the third; 43 the fourth; then 114, 125, 205, 283, 324, and 465 in as many successive weeks.

Milwaukee has a well organized health department that charts its contagions, placards affected areas, and carries out assiduously other accepted procedures under such conditions on the basis of cases reported by physicians as required by law. In the schools this health service is supplemented by a medical and nursing personnel of seventy-five persons, but the degree of medical supervision it is possible to administer to seventy-five thousand children by seventy-five people is about as effectual a preventive measure as the placarding of only the frank cases of contagious disease.

When it is desired to kill a plant pest, or to rid a community of rodents or vermin, measures of extermination

are based upon exact knowledge of the life cycle and habits of the pest. Knowledge is not lacking on the part of scientists of the precise curves that mark the rise of epidemics, but in the case of contagious disease this knowledge is not put to work. The usual channels of communication for the more common diseases and the periods of incubation are not popularly known. Placarding and isolation are delayed until definite diagnosis becomes possible, and contacts for the most part remain unlimited during the period best calculated to favor the spread of the disease.

School medical inspection by experts may reasonably fail in the case of Milwaukee, because it is physically impossible for one physician or nurse to inspect daily—at the beginning of the school session—the one thousand persons allotted to his care.

However, Shorewood, a suburb of Milwaukee, has found a satisfactory solution. During the former measles

The new Shorewood School has a completely equipped clinic, with facilities for health building as well as health guarding.

for the Medical Profession Exclusively.*

epidemic, when Milwaukee as a whole exhibited eight thousand cases, Shorewood had six. So far this year Shorewood has not reported a single case. During the following year not one child, while attending school in Shorewood, contracted whooping cough, scarlet fever, or any other disease common to children, and only one child carrying contagion with it managed to get into the single parochial school in Shorewood. That one child created enough mischief to account for about one-fifth of the total reportable diseases during the year. The record of the schools for the three succeeding years was equally good.

Shorewood takes the position that the school must not be permitted to constitute a health menace to the growing child, that the children have a right to go back from school at night as well and as free from the infection as when they left their homes in the morning. No agency other than the school has either the machinery or the contact with the public to make comprehensive or adequate health work possible. The teachers, therefore, are constituted by the health department with the proper authority under the leadership of the medical inspector and are held responsible for the health of their charges. Every teacher has full information of all epidemic conditions known to be brewing and is advised as fully as may be of typical signs and of the period of incubation. This information is likewise passed on to the parents. In the daily routine inspection of children as they enter the rooms, every child is excluded who shows signs of a cold, running nose, or watery eyes. Measles starts with symptoms of a common cold. If the affected child is not isolated at an early stage of the disease, and isolated before definite diagnosis can be made on the basis of clinical signs, the psychologic moment to protect the school from invasion has gone, and control becomes impossible.

#### Placard on Suspicion

The channels of communication must be broken before diagnosis is made, and long before definite diagnosis can be made placarding "on suspicion" is utilized. The physician is not asked to hazard a guess before diagnosis on the basis of clinical symptoms is possible. It does not matter what the case is called, so long as it is isolated. Therefore, in the case of a measles epidemic, a small card goes up "Measles suspected." The bill board type of placard is

never used except in the event of an attempt to break the quarantine, when the usual machinery, and police power back of it, are called into action for the necessary control. The poster sign is then placed at the back of the house merely to conform to the law.

It is desired in every case to secure voluntary cooperation. A basis for intelligent cooperation is laid down in the health education of the children. Fifteen minutes every day are devoted to health work. The specific conditions of threatened diseases are taught, the cause and effect of exclusion are emphasized, and the "why" of any seemingly radical measure is always fully explained so as to obviate at the outset any unnecessary opposition. The schools in Shorewood can always be relied upon to disseminate the knowledge upon which intelligent cooperation is based. The spirit of prevention of needless attacks of communicable disease has so far permeated the community that health, school, and medical machinery are correlated. The physician now reports suspected cases, and parents who formerly concealed cases of contagion, now call for placards and report on conditions in their neighborhood.

Clearly it is a question of community ethics. The medical profession affords the leadership, the school, the machinery, and it is now a matter of opprobrium to permit contagion to pass to a second family. Indifference to this ideal is in Shorewood becoming as unpopular as theft, or fraud, or violence. To expose a child to contagion is popularly characterized as a violation of human rights. The needed knowledge to make effective a health program is the basis of public action, and the neighborhood itself is now in a position to deal with neighborhood foci.

W. C. Sieker, a citizen first, became health officer of Shorewood by accident. There is nothing fortuitous, however, about the success of the activities of his department over a period of five years. The morbidity curves of the city at large are not the morbidity curves in Shorewood, all because of the unique health machinery of the schools. This work is now being supplemented by a school laboratory and a school bacteriologist. A far sighted program of positive school health will be furthered likewise by nutritional work under a graduate in home economics, but that is another story.

The devastating effects of epidemics on community health are comparatively easy of control in small towns

and isolated communities, according to Mr. Sieker, but the problem of contacts is much more complicated in the suburb of a large city where communication is more or less constant between the ever present foci of infection. In a city suburb there is the added difficulty of never being able to relax on measures of popular education, for the population of Shorewood, a typical city suburb, shows 20 per cent growth each year. The shifting population always offers a constant problem in fostering a community feeling and maintaining the necessary uniformity in community ethics.

#### Cults Present Obstacle

There is no unique condition of enlightenment or better standard of living in Shorewood other than the drastic methods employed to exclude contagion that would account for the low morbidity rates that have obtained in the last five years. Economically, conditions differ in no way from those sections which adjoin it, the Eighteenth Ward or in the Washington Park district. Because of its cults. Shorewood is in a way more difficult to control than foreign wards where the people understand the force of law and obey the health officer's dicta. Certain of the cults have asked the privilege of foregoing physical examination for their children, a request which has been granted provided the parents themselves would undertake to keep at home the children who showed signs of colds. The distinct reservation has been made, however, that in the event of diphtheria, no exception would be made in cultures taken to discover possible carriers. The successful abortion of a diphtheria epidemic last year by the discovery and removal of fourteen carriers precluded any objection to this reservation. The rules imposed by the Shorewood health board go beyond the state laws. Power has been granted in the village that health regulations posted four or five days become operative as laws. This provides for emergent measures. Ordinarily, however, flexibility is desired and the position is taken that education and high ethical standards rather than force should govern. The citizens themselves report by telephone in regard to conditions calling for investigations. No names are given or asked for, and no spy system is in force, for the same citizens hasten to report conditions in their own families. In point of fact, five years of health demonstration have made the community health conscious, and all are health propagandists.

# What Stanolene Purity Means

Stanolene Petroleum Jelly is absolutely pure. This means that it is refined by a special process, evolved after years of study, and exclusively used by the Standard Oil Company (Indiana).

## STANOLENE PETROLEUM JELLY

*The White Petrolatum That Is White*

is refined with the highest degree of scientific accuracy, skill, and precision. Every impurity, every irritating and deleterious substance is removed.

Only a certain, carefully selected type of petroleum is used for the production of Stanolene. As a result of this care and scientific labor, Stanolene Petroleum Jelly is of unequalled velvet-like smoothness, non-irritating and soothing to the highest degree.

Stanolene is both odorless and tasteless, is agreeable for internal use, and excellent as a base for salves and ointments.

Stanolene is snow-white, clear and translucent, ideal for use in all compounding work where absolute uniformity of color is desired.

The most scientific physician may recommend and prescribe Stanolene with entire security that it will justify his patients' expectations. For office use physicians will find the half pound and the pound packages convenient. If you have not received your physician's sample, write us and it will be sent promptly.

## Veneral Diseases in Eastern Europe

Health authorities and intelligent people in eastern Europe are more than ever before alive to the prevalence and seriousness of venereal diseases as an impediment to individual and national health and happiness. Countries invaded by foreign armies during the war attribute the seriousness of their present problem to the invaders, and the invading armies are, on the other hand, blamed for the increase of infection which follows their return home. Whatever the truth of these accusations may be, it is quite certain that armies not controlled as the American army was during the world war, after infecting themselves do distribute and increase the amount of infection in the civilian population.

In an account of the problem of the social diseases in eastern Europe, Walter Clarke writing in the *Journal of Social Hygiene*, states that in war-shattered Belgrade valiant efforts are being made to relieve the distress caused by inadequate facilities with which to care for poverty-stricken people infected with venereal diseases. The same anxiety to cure and prevent syphilis and gonorrhoea is evident in Sofia, Bucharest, Prague, Warsaw, Riga, and Constantinople. The health authorities and other leaders of public health work in these cities are sufficiently alive to the needs of infected persons, but the difficulties which stand in the way of effective measures are not likely to be overcome without a long struggle.

The lack of medicaments due to the low purchasing power of the debased currencies of eastern European countries and the lack of physicians are the greatest obstacles in the countries of east and southeastern Europe to the establishment of adequate and sufficiently numerous treatment centers. Sufficient arsenical compounds for the treatment of syphilis are produced in England, France, and Germany to supply the needs of Europe, but the almost worthless paper money of countries like Poland and Rumania has prevented the general importation of sufficient quantities of these needed supplies. The continued depreciation of the German mark, however, has made it possible for countries having debased currencies to purchase German drugs, and these drugs are now in general use in the Balkan States and eastern Europe.

The problem of trained personnel is a matter that cannot be quickly remedied. It is in Rumania, Bulgaria, and the Baltic states that the need is the

greatest. An appeal has been made to the League of Red Cross Societies to furnish doctors to accompany mobile units which it was proposed to send from village to village treating the general population, syphilitic children, who are very numerous, being given special attention. Lack of the needed funds made it impossible for the Red Cross to accede to this request.

Constantinople is, according to Mr. Clarke, in the most tragic position of any city outside of Russia; the establishment of a medical school at Sofia will in time relieve the dearth of physicians in Bulgaria; health education is well supported in Jugo-Slavia; recovery is proceeding rapidly in Czechoslovakia; Poland is on the way to recovery; but Latvia, Esthonia, and Lithuania lack almost everything which is needed for good health work.

Fortunately for these three small republics, however, their venereal disease problem seems less acute than in the other countries mentioned.

In Poland, tuberculosis was as serious a problem as was typhus even during the epidemic years. Syphilis like tuberculosis is not spectacular and is even more difficult to control than typhus. The governments of eastern Europe are now awake to the ravages of the venereal diseases and as economic conditions improve will no doubt take steps to provide adequate instruction, diagnosis, and treatment for the people. The present adverse economic conditions have restricted their efforts to a minimum, yet, what they are doing compares favorably under the circumstances with the activities of western European states.

## British Doctors Discuss Milk

BY OUR LONDON CORRESPONDENT

**B**OVINE tuberculosis, pasteurization, and dried milk were topics of discussion before the British National Clean Milk Society which convened in the historic council chamber of the Guildhall, London, for three days beginning October 15.

Sir Alfred Mond, then Minister of Health, stated the desirability of having milk free from tubercle bacilli. The bill he had succeeded in passing through the House of Commons would give the people the right to insist upon milk of a certain standard.

The doctrine that small doses of tubercle bacilli taken in milk during childhood might have an immunizing effect upon human beings was rejected by Dr. A. Stanley Griffith, research bacteriologist to the Medical Research Council as too dangerous to the child since even a small dose might set up fatal tuberculosis. It was pointed out by Dr. Nathan Raw, M.P., that at present tuberculosis germs were found in about 15 per cent of all the milk supplied and that if the Milk Act recently passed could be carried into effect the danger to children would be almost completely removed.

The morning session was devoted to various papers setting forth the advantages and disadvantages of a pasteurization and other methods of treating milk. Prof. Georges Dreyer, professor of pathology in Oxford University, pointed out the danger of keeping the milk so heated too long. He stated that dried milk would be

a boon to the industrial centers because it was a good substitute for raw milk. Dr. Robert Hutchison stated that it was his opinion that the decline of deaths from infantile diarrhoea in recent years was due to the ever increasing use of dried milk for infant feeding especially among the working classes. Dried milk was found to be much less liable to contamination in the home than wet milk was his further contention.

Pasteurization as a means of preventing the spread of infectious diseases, such as typhoid fever, septic sore throat, scarlet fever, and diphtheria was urged by a paper by Dr. Charles E. North, of New York, read by Colonel Barham. Infection of the udder in dairy cows constituted by far the most serious menace to the public health originating from dairy cattle the paper stated. Since the adoption of pasteurization in New York, the death rate of infants under one year of age had been reduced from 165 to 1,000 born to 70 per 1,000 born. Dr. Eric Pritchard testified to the belief that pasteurization did not destroy the milks' nutritive value.

Dr. Leonard Hill, director department of applied physiology, Medical Research Council, stated it as his opinion that dried milk had created a revolution and that distribution by grocer or some similar agency would eliminate the milkman and so reduce the cost of supply.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

### For Impartial Clinical Study of the Cults

The issues in the recent election which in certain states seem to threaten the prerogatives of scientific medicine are important enough, says Dr. Channing Frothingham, of the faculty of Harvard Medical School, to justify a demand on the part of the medical profession that the claims of various cults for efficacy of method be submitted to precise clinical and laboratory investigation. Until some basis of fact is presented, they cannot be evaluated as methods of treatment, nor can any referendum to popular vote on privileges of lower educational requirements for license to practise their healing arts be properly conceded. Under the title "Osteopathy, Chiropractic, and the Profession of Medicine," Dr. Frothingham's summary of the situation as it exists today was utilized by *Colorado Medicine* in its activities on the issue in Colorado.

"Attempt has been made to show that, in both these professions, there is something of value in the treatment of certain diseased conditions, even if the exact method by which this benefit is obtained is not understood. It has also been attempted to show," says Dr. Frothingham, "that these professions can in no way replace the established facts of medical science; and that those using these methods of treatment should have the same general knowledge of medicine that is required of the regular physician in order to safeguard the individual and the public health."

It is made plain that the work of neither of these two cults rests upon any proved scientific basis; that they have not done any experimental work to prove their theories, and that as practised today by men uneducated and untrained in pathology, in physiology, and in the scientifically proved facts about many diseases, they are a menace to public health. Dr. Frothingham considers that the methods used should be scientifically investigated. When any sect in the healing art becomes strong enough to gain general public recognition over large territories, it is worthy of critical study by capable scientists in order that the truth may be known and therapeutic measures of value become available to the general medical profession which is best prepared to assign them to their proper spheres in the treatment of the sick. By its readiness to act through a properly constituted body, scientific medicine can and should know the clinical values or nullities of widely heralded systems of treatment. It should likewise be in position to speak advisedly against worthless measures.

With the average American citizen, the plea of the under dog outweighs any argument that may be advanced as an *inse dixit* in the name of science. The medical profession should therefore play fair to the extent of

carefully investigating systems which *a priori* seem to it devoid of merit. It can afford to be magnanimous. Under a democratic form of government it cannot afford to refuse to ascertain the value of innovations and stands condemned before the laity if it persists in such refusal. It should without prejudice use therapeutic measures of proved value irrespective of where found and by whom promulgated. In this way may it gain full confidence of the public. It may at the same time eliminate any reasonable excuse for the recognition of men devoid of scientific training who practice systems of limited or questionable use.

In order to meet the issue there is at present a move on foot to create a commission of capable scientists of judicial temperament to investigate clinical results of treatment by schools of healing of wide popular recognition. The effort is to make this commission, as far as humanly possible, efficient and free from bias. Its selec-

tion and methods of procedure should be determined by representatives of the national medical bodies working in conjunction with representatives of the American Bar Association, the National Educational Association, the Association of American Universities, the Rockefeller Foundation, the Carnegie Foundation for the Advancement of Teaching, and such other standardizing agencies as may be deemed best to invite or can be interested, to the end that its findings may be given the widest possible credence by all thinking people.

The Federation of State Medical Boards of the United States stands sponsor for the general movement and the various organizations mentioned are being invited to send representatives to a conference to consider ways, means of organizing and direction of such commission. The American Medical Association and the American Institute of Homeopathy have approved the undertaking by official action and it is hoped that the others will comply.

## Antivivisection and Health

THE defeat of the antivivisection measure by the voters of California at the polls November 7 was due largely to the effective education campaign carried on against the proposed law by the medical and public health professions. The dependence of health on vivisection is clearly pointed out by David P. Barrows, president of the University of California, speaking for the board of regents, and by Ray Lyman Wilbur, president of Leland Stanford University, speaking for the board of trustees. Their statement herewith from the *Journal* of the American Medical Association urging the people to vote "no" on the proposed measure is typical of the sane and scientific attitude on this question:

The advance of sanitation, modern medicine and physiology, nutrition, the teaching of biology and the protection of our industries and agriculture all rest on animal experimentation. The control of the epidemic diseases of man and of animals, the management of surgical operations and of childbirth and the certification of milk, food and water supplies would be impossible without the knowledge gained by such studies. In fact, the present day protection of the public from diseases, which is vital to our community life, rests on animal experimentation.

Not only would it stop the research work now going on in the medical schools, hospitals and laboratories and in the Bureau of Animal Industry, but it would damage the market for most of California's food products, and markedly reduce the confidence of visitors coming into the state. If California could not certify to its foods and water supplies, could not guarantee protection against contagious diseases, could not provide certified

milk, the effect on agriculture and industry in the state would be disastrous. The near collapse of the olive industry, due to the poisoning of a few people in eastern states, and the way in which the industry was saved by the researches carried on in the laboratories of the two universities, indicate the imperative necessity of freedom for the universities in animal experimentation. California food, instead of being looked to as an example of purity, would be shunned.

The initiative measure would make it impossible to test with birds for deadly gases in the mines of the state. It would stop the manufacture of serum for the prevention of hog cholera, the preparation of vaccine for anthrax, and the various other products that are required for the protection of our industries in agriculture and that annually save millions of dollars and prevent great mortality among domestic animals. Under the act, operations on various farm animals could be carried on without anesthetics to increase the palatability of foods, but no animals could be used in experimental work if the information obtained is for the benefit of a person or of the human race.

We feel that no worse attack on the welfare of the state and on the right of the universities to seek and teach the truth could be made. Every man, woman and child, every unborn babe, every domestic animal in the state would be affected if this measure becomes a law. It strikes at all. It is unnecessary special legislation, due to prejudice and misinformation. No one will tolerate cruelty to animals. The present laws of the state are drastic and sufficient to control any abuse. We know that there is no cruelty to animals in the laboratories of the universities.

Anesthetics are always used for animals in the laboratory in exactly the same way that they are used by surgeons in the operating rooms.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

## FROM THE FIELD

The Child Health Organization of America through the MacMillan Company has published "Everychild's Book" by Mrs. Frederick Peterson and illustrated by Jessie Gillespie. The book is paper bound and published on heavy glazed paper. The verses, one for each letter in the alphabet, and illustrations are suitable for primary children.

A two years' evening training course in the fundamental principles of physical education is being given by the division of physical education, board of public education, Philadelphia. The course takes up the theory of organization and administration, the philosophy of play, and in addition gives opportunity for practical work.

Motion pictures have become the subject of research in several large universities states *The Playground*. The Universities of Chicago, Wisconsin, Oklahoma, Kansas, and Columbia University have conducted scientific inquiries into the motion picture as a means of classroom instruction. It has been found to be effective especially in the study of the psychology of reading and writing. Thirty-four cities are using educational films in classrooms and assembly halls. New York spent approximately \$10,000 for this purpose last year, while Los Angeles spent \$25,000.

To furnish apes for medical experiment the Pasteur Institute is establishing a reservation in French West Africa where anthropoid apes will be able to breed and thrive unmolested. Because they are the only animals that contract certain diseases to which men are subject, large numbers are used for experiment. Laboratories will be built on the reservation where experiments can be carried out without costly transportation. Dr. Wilbert, a young French bacteriologist, has been appointed by the institute to start the ape farm.

In the development of various forms of betterment work in industry, music has been increasingly employed because of the view that it exerts a vital influence on employee psychology, according to the National Industrial Conference Board. The idea of

associating music with industry began in factories with the gathering of small groups to sing at the noonday lunch period, and has grown into a well-developed movement for organized music in many of the leading industrial establishments of the country. A Chicago concern which now has ten minutes of chorus singing at 10 a. m. and another ten minutes at 3 p. m., reports that the former excessive labor turn over and absenteeism practically has ceased. Several Detroit factories are said to have effected a 10 per cent increase in output by the introduction of music in working hours.

As conditions existed in 1920 it required more than 100,000 of the population to supply the professional schools of the country with one student of veterinary medicine, 23,000 to supply one student of pharmacy, 15,000 to supply one student of theology, 12,000 to supply one student of medicine, 5,000 to supply one student of law. There were in 1920, 78 medical schools with a total of 14,800 students and 106 law schools with 20,842 students, according to Statistical Abstract of the United States, 1921.

The Joint Administrative Board of Columbia University and the Presbyterian Hospital announces that the site for the new Medical Center has been transferred to the University and the hospital. The land site extending between 165th street and 168th street, from Broadway to the Hudson River, is in excess of twenty acres and is valued at about \$4,000,000. It was given by Mrs. Stephen V. Harkness and Edward S. Harkness.

Warning against attributing every pathologic state which appears during periods of deficient feeding to insufficient intake of vitamins is sounded by P. G. Shipley, in the *Journal* of the American Medical Association. Deficiency diseases are caused not alone by the lack of vitamins but by too low feeding of protein and often to improper amounts of carbohydrates and salts, he states.

The Massachusetts department of public health with the assistance of the Massachusetts child labor committee has published a pamphlet "That Depends" which urges health

certification backed by thorough medical examination of children going into industry.

Senator Lodge advocates a national law, patterned after the Massachusetts 48-hour statute, limiting the hours of labor for women and children. He also favors a constitutional amendment prohibiting child labor, if a bill regulating employment of children can not be framed to meet the approval of the Supreme Court.

The teaching of physical education in the public schools of Michigan is mandatory. The term is interpreted to mean anything which will better the physical condition of the children and includes in its scope the teaching of health habits, free and directed play, games, and relaxation periods. Floyd A. Rowe, state director of education, is the author of a pamphlet "Physical Education for Elementary Schools" which contains numerous games and physical exercises for younger children.

A conference to discuss ways and means of assisting the mental, moral, and physical development of the nation's youth was called by Secretary of War Weeks at war department headquarters November 16. The Boy Scouts, Y. M. C. A., Red Cross, and state and municipal authorities were represented.

"Poisoned pie policies" are now offered by a New York firm of insurance brokers to protect restaurant and delicatessen owners from the scores of damage suits filed yearly by persons who claim, often fictitiously, that food procured from these establishments has poisoned them.

Though smoking may injure the finest reactions it does not retard the ordinary worker is the finding of an exhaustive inquiry into the effect of tobacco on smokers conducted in the psychological laboratory of Johns Hopkins University by Dr. Knight Dunlap and associates.

An international labor directory of government bureaus and employers' and employees' organizations in forty-seven countries has been issued by the International Labor Office at Geneva. The directory also includes the organization and personnel of the council and the assembly of the League of Nations and of the International Labor Organization.

# Weight

**W** EIGHT is an important factor in physical examination, diagnosis and treatment. An accurate scale is a necessary part of the equipment of the industrial or school physician, public health official, visiting nurse or other individual doing field health work.

When accuracy can be combined with ready portability as has been done in our spring platform scale the ideal outfit is obtained.

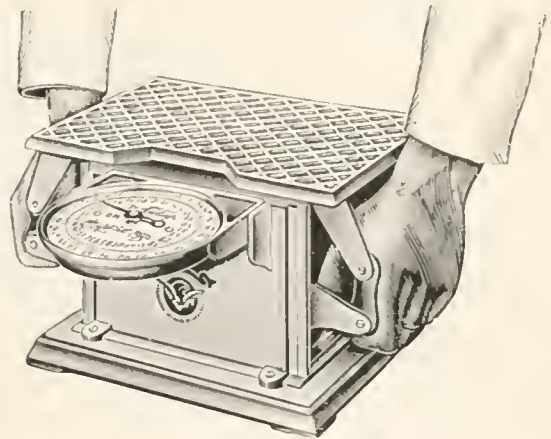

Self weighing is possible by merely tilting the dial; the dynamometer test aids both diagnosis and examination.

**Takamine**  
Toothbrush

**Good Health**

DEPENDS largely upon good teeth. To have good teeth you must brush them at least twice a day with the RIGHT toothbrush—one that cleans ALL the teeth.

The average toothbrush has a 2-inch brush which is too large to move over the molars freely and remove the bacterial masses that cause decay. The bristles merely bend or pivot on these teeth. The Takamine Toothbrush is endorsed by dental authorities as the RIGHT toothbrush because it is just the RIGHT size—1 inch long with 1/4 inch bristles.

It easily reaches and thoroughly cleans EVERY TOOTH.

Dentists furnish Takamine Toothbrushes to their patients; public schools to their pupils.

PRICE, \$7.00 A GROSS, DELIVERED.

*In Less Than Gross Lots, 5c Each, Plus Postage.*

**TAKAMINE MFG. CORP.**

**Occupation  
Therapist  
and Aides  
Curtail  
Your Waste**

*A Message from Mrs. Clyde M. Myres*

After years of experience in organizing and conducting occupation therapy in hospitals in France, Panama and United States I feel assured that the methods proposed by the American Reedcraft Corporation of handling Reed and other materials will be of inestimable value to the Reedworker in the Hospital, Home or School. To supply models and instructions for making the various articles of reed and other fibres with the amount of material including everything from the base to the finishing dye or stain will be a saving of labor and time and also eliminate waste of material. It will be undoubtedly a great aid to the occupation therapist, as well as to the individual reedworker. Very truly yours,

MRS. CLYDE M. MYRES.

Write for your copy of our Latest Price List.  
**AMERICAN REEDCRAFT CORPORATION**  
"Everything for the Reedworker"  
130 Beekman Street NEW YORK, N. Y.

The Universities of Manchester, Leeds, Edinburgh, Cambridge, Durham, and London, and the Royal College of Physicians of London now grant diplomas in psychological medicine.

Mental, physical and social welfare problems relating to the people of Illinois were discussed by the Illinois Conference on Public Welfare at East St. Louis, November 12, 13, and 14. Among the speakers were Dr. Carl C. Chatterton of St. Paul, Minn., who spoke on the state care of crippled indigent children.

A new clinic has been opened by the U. S. Veterans' Bureau at Huntington, W. Va., under the direct supervision of Dr. L. V. Guthrie, superintendent of the Huntington State Hospital. The building is entirely separate from the state hospital and is used exclusively for ex-service men, claimants of the bureau. It is equipped with all modern apparatus for the care and treatment of the different forms of psychosis and is identical with the clinics at Marion, Va., and at Catonsville, Md.

The U. S. Veterans Bureau has established schools for physicians at St. Elizabeth's Hospital, Washington, D. C., for the treatment of mental diseases and a physician's school for the treatment of tuberculosis is at Oteen, N. C. Expenses for the two schools will come from the Bureau's general fund, Colonel Charles R. Forbes announces.

A study of the U. S. Department of Labor dealing with conditions which attended the entrance into working life of 5,692 children in Boston, Cambridge, Somerville, and Chelsea, Mass., shows that both child and community are losers when children under the age of 16 are gainfully employed. Such children have not sufficient education to make them adaptable to changing industrial conditions or to give them an understanding of the duties of citizenship.

The California Association of Physiotherapists has appointed a commission to survey the schools of Europe and America giving courses in physiotherapy or related subjects; to survey educational and practical conditions of physiotherapy in the state of California; and to draw up a complete bibliography of physiotherapy literature.

*The American City* reports the decision of the United States Circuit Court of Appeals, Fourth Circuit, which upheld the action of a county board of health in North Carolina which prohibited circuses and carnivals in a county during a certain period to prevent the spread of communicable diseases. The resolution of the board of health stated that the county was just recovering from a serious epidemic and that communicable diseases were prevalent elsewhere. The owner of a traveling show brought suit when a license was refused him but the court sustained the action of the board of health.

Only one and one-half per cent of the bills and resolutions introduced in the sixty-seventh congress were concerned with national health. During the two sessions of this congress, the first session of which convened in April, 1921, and the second session of which adjourned on September 22, 1922, over 18,000 bills and resolutions were introduced in both houses. Of this number, less than three hundred pertained to public health. Five hundred and eighty-seven bills and resolutions became laws but only about 25 of these were measures of direct interest to sanitarians. Statement No. 36 issued by the National Health Council contains a review of the national health legislation before congress.

The Illinois state department of public health is conducting a correspondence course of instruction for district health superintendents and local medical health officers. As a supplement to this course, a weekly health index will be placed in the hands of those on the mailing list.

Physicians and residents of Baltimore County, Maryland, are organizing a county health association to take over the work formerly conducted by the Red Cross. Dr. William E. Bridges, superintendent of Eudowood Sanatorium, is chairman. A committee of five has been appointed to confer with officials of the Baltimore County Children's Aid Society and other organizations on forming a health association. The new organization will furnish a nursing service throughout the county. Assisting Dr. Bridges on the committee are Dr. Frank W. Keating, superintendent of Rosewood State Training School, A. D. Stebbins, Dr. W. P. E. Wyse, and S. Duncan Black.

"Matty Wins His Greatest Game" is the title of the 160-foot motion picture film to be released by the National Tuberculosis Association in connection with the Christmas seal sale. The trailer shows the hero in the days when he was the greatest pitcher, the announcement of his illness follows, and the film concludes with pictures of "Matty" after his recovery from tuberculosis.

Colds, rhinitis, headache and sore throat constituted 35 per cent of all calls to the dispensary, whereas colds, septic throat and headache, plus their more serious developments (influenza, grippe, pneumonia, laryngitis and tonsillitis), were responsible for 41 per cent of total time lost on account of sickness. Indigestion induced 5.4 per cent of total dispensary calls, and contributed 4.5 per cent of all time lost on account of disabling illness.

As a part of the program of the division of maternity, infancy and child hygiene of the state department of health, eighteen classes have been formed in various parts of New York state for the special instruction of public health nurses in the hygiene of maternity.

The following members of the board of directors of the American Child Hygiene Association have been appointed by President Herbert Hoover to prepare with a similar committee from the Child Health Organization a constitution for the merged organization: Homer Folks, chairman, Dr. Philip Van Ingen, secretary, Bailey B. Burritt, Dr. S. McC. Hamill, and Mr. Hoover. Dr. Livingston Farrand and Dr. Richard M. Smith are alternates.

A new mental clinic, the fortieth now in operation under state hospital auspices, has been established in Batavia, N. Y. by the Rochester State Hospital.

That whooping-cough in view of its complications and sequelae and its high mortality rate should be regarded as a major communicable disease and that parents and physicians should be instructed and urged to recognize that strict quarantine is essential is the recommendation of the committee appointed by the New York City health commissioner to consider the use of vaccine. Members of the committee were Drs. J. J. Blumenthal, Robert J. Wilson, L. H. Harris, and Wm. H. Park.

# An Ideal Christmas Present for Your Co-Worker

Would you like to express your appreciation of the interest and effort that has been displayed by someone who has worked with you or for you in the past year?

Would you like to send a Christmas gift to such a friend who is active or interested in some phase of group health as you are?

If so, a year's subscription to The NATION'S HEALTH with the suggestions and really practical discussions of health problems that are to be found in each issue, is the ideal kind of Christmas gift. It is an expression of friendship in each month of 1923, as the twelve different copies arrive.

Our announcement saying that you have directed us to send The NATION'S HEALTH for the new year will be delivered on Christmas day if the attached coupon is mailed to us at once.

### Forty Notifiable Diseases

A small book by Dr. Hiram Byrd contains a simple discussion of the more important communicable diseases. Technical terms have been largely omitted as the book is intended to be a summary of the important facts that should be a part of the knowledge possessed by every citizen, and deals only with those aspects of the subject that a layman can reasonably be expected to assimilate.

After a brief discussion of the nature of germs, forty of the notifiable diseases are classified according to the nature of the causative agent, viz. known vegetable germ, known animal germ, germ not known, and filterable virus. The remainder of the book is devoted to brief treatments of the nature of each of the diseases, together with such information as will aid the reader to escape infection or to cooperate with the physician when misfortune does befall.

World Book Company, Yonkers-on-Hudson, N.Y., 1922.

### The Evolution of Public Health Nursing

Historical works by specialists who are professional historians are likely to furnish the unassimilated raw materials rather than the digested conclusions of history. This is not the case with Miss Annie M. Brainard's book. It is not only accurate but judicious and it shows the rare power of vision which presents the story of a movement in clear relief and in right relation to other tendencies of the times.

The outstanding points in the history of visiting nursing *per se*,—the work of the Deaconesses in the early church,—the foundation of nursing sisterhoods by St. Francis de Sales and St. Vincent de Paul,—and the stimulus to a similar work in the

Protestant Communion by Pastor Fliedner at Kaiserswerth,—are first discussed. Then Miss Brainard outlines in a most illuminating way the development of the new practical humanitarian movement of the early nineteenth century and of the still more novel conception of prevention due to the early English sanitarians, and shows how the fusion of these constructive ideals with the instinct of service which actuated the religious nursing orders gives us the public health nurse of the present day. The spread of district nursing in England and the important influence there of the National (later the Metropolitan) Association for Providing Trained Nurses for the Sick Poor are admirably presented, as are the pioneer efforts made along similar lines in the United States at Charleston (1813), at Philadelphia (1829), at New York (first actual visiting nursing done by the City Mission in 1877) and in Boston and Philadelphia (where for the first time organizations were formed for the primary object of instructive district nursing almost simultaneously in 1886).

The last quarter of Miss Brainard's book, dealing with progress during the past ten years, suggests some haste in preparation. It contains much valuable information but in future editions should be reviewed with the perspective which characterizes earlier chapters and supplemented by fuller discussion of the return to generalized nursing after twenty years of fruitful experimentation with specialization, and of the important recent tendencies in nursing education.

New editions there will surely be for this volume presents a story of the development of public health nursing up to 1910 which will remain a classic.

W. B. Saunders Company, Philadelphia, 1922.

### Urge Grading of Milk in New Jersey

With milk-selling conditions in New Jersey represented as chaotic, the department of agriculture and the public health department of that state counsel the adoption by municipalities of a recognized standard of grades for all milk sold in the community. Confusion is said to reign in many communities because of the absence of well-defined grades and fraudulent practices have become more or less common in some sections, in the sale of milk under terms which misrepresent the true facts, officials say.

"The Legislature has granted full authority to the state and the local boards of health to take such steps as are necessary to protect the public against unclean and unsafe milk supplies," says a statement from the New Jersey department of agriculture, "but, while numerous local boards have adopted certain restrictions, there has been heretofore no fixed standard.

"With more stringent health laws governing the conditions under which dairy herds are kept and milk handled, the cost of milk production has increased. Health officials, too, have been divided into two schools, one division favoring pasteurization of milk, the other for the sale of pure, raw milk. The proposed plan of standard grades permits both."

The proposed standards have been unanimously approved by the New Jersey Federation of Women's Clubs, the League of Women Voters, the New Jersey Health Officers' Association, the New Jersey Federation Boards of Agriculture, the Interstate Milk Producers' Association, the Dairymen's League Co-operative Association and the New Jersey Holstein-Friesian Cooperative Association.

*A Dignified  
 Service*

Few periodicals of any type have developed a classified advertising standing equal to that of THE MODERN HOSPITAL.

It is a unique achievement. Hospitals and people in the hospital field have, by their repeated use of our columns, broken down the impression that want ads are undignified.

Have you tried a classified advertisement in THE MODERN HOSPITAL to help you dispose of some used article? It has served many superintendents very successfully in this way.

Let the classified advertising columns of THE MODERN HOSPITAL be of service to you.

THE MODERN HOSPITAL  
 PUBLISHING COMPANY

Inc.

Chicago, Illinois

*Neosalvarsan*  
TRADE MARK REG. U.S. PAT. OFF.

(Neoarsphenamine-Metz)

is unsurpassed in reliability, trypanocidal efficiency, and ease of administration.

Neosalvarsan is manufactured by the process used in preparing the original Ehrlich product and offers the physician the ideal means for treating the luetic.

H.A. METZ LABORATORIES, INC.  
125 HUDSON ST. NEW YORK

## North Shore Health Resort

Dr. Eugene Chaney, Medical Director  
 Dr. Georgina A. Grohan, Ass't Physician  
 Dr. Anne H. M. Sharpe, Ass't Physician

**Winnetka, Ill.**  
 16 Miles North of Chicago

W. R. WHITAKER, *Manager*

**W**ELL appointed Sanitarium located on the shore of Lake Michigan. For the care of Convalescents, Treatment of Nervous Diseases, Insomnia, Affections of the Heart, and Disorders of the Stomach and Kidneys. Complete Clinical Laboratory with modern High Frequency Outfit—Nauheim Baths—Electric Cabinet Baths—Shower Baths—Medical Gymnastics—Massage and Electricity, etc. Large recreation grounds, bathing facilities, outdoor sports.

*Write for Booklet*

Telephone—Winnetka 211

Grand View Health Resort, Waukesha, Wis., famous for its splendid mineral waters.

## Moor (Mud) Baths

For RHEUMATISM, GOUT, LUMBAGO, ARTHRITIS SCIATICA, NEURITIS, DIABETES, GALL BLADDER and LIVER TROUBLES, ECZEMA, and other ailments that require Good Circulation, Elimination, Relaxation, and Rest.

FIREPROOF and MODERN BUILDING. We co-operate with the home physician and are glad to receive his suggestions. Correspondence with Physicians Solicited.

*For Rates, Literature and Reservation, Address*

**Waukesha Moor (Mud) Bath Co., Waukesha, Wis.**

OPEN ALL YEAR ROUND

## Health Insurance After Sickness

The superintendents and staff physicians of many hospitals now advise convalescent patients to make use of the facilities of the HOMESTEAD before resuming their customary duties.

This procedure is very beneficial to the patient since it insures complete recovery and gives health insurance after illness or operation.

The convalescent who comes to The HOMESTEAD at Hot Springs, Virginia, is assured of a post-hospital treatment that cannot be surpassed anywhere in the world.

The HOMESTEAD is a health resort that provides all approved forms of Hydrotherapy, Radium Emanatorium, Inhalatorium, Solarium, Zander Institute, Diet Kitchen—all these in addition to exquisite appointments, complete service and grandeur of scenery.

The Calcic Carbonate, Magnesia Carbonate, and Sulphate Springs located here are all radioactive. The springs emanate from the ground at a temperature of 106 degrees.

All required medical attention is available. And for those able to indulge in active diversions there are riding and driving, trails through the picturesque Allegheny Mountains, tennis courts and two golf courses.

Let us send you illustrated, descriptive literature.

# Now! A Butter Guaranteed to Keep!

Heathized Butter is sold everywhere under the guarantee it will keep fresh and sweet until used. No other butter is sold under such a guarantee because ordinary butter, always churned in air, oxidizes rapidly and develops off flavors. The following article reproduced from the Medical Times tells why you should demand butter made the Heath way.

*Reprinted from "The Medical Times".*

## THE AIR CONTENT OF BUTTER

JACQUES W. REDWAY, F.R.G.S.,  
Mount Vernon, N. Y.

About ten per cent of the volume of butter consists of air. Air and its dust content is carried into milk at the moment of milking. Still more is blown into it during the cooling process. Another addition is made at the separator. Some is churned into it—a considerable proportion, in fact. In the kneading process air is worked into the butter; it is likewise kneaded out.

The effect of churning air into food product is illustrated in the case of fabricated ice cream. Six or seven gallons of the fabricated mixture is put into the freezer and churned or stirred until the volume is increased to ten gallons, by the addition of air.

Now, if the air that is churned into butter were pure and free from dust, one might assume that the occluded air would be harmless. Perhaps this might be the case, but experiment has shown that the contrary very probably is true. Butter exposed to the air becomes rancid unless a preservative is added. So does butter packed tight in firkins. It is the air within quite as much as the air without which causes the change. It is oxidation as well as putrefaction.

The Department of Agriculture has presented some figures worth noting. Freshly churned butter was analyzed as to its free oxygen content at measured intervals. When the butter was kept in still air at a temperature of 32° Fahrenheit, the changes in the amount of free oxygen were slow. An average of many samples showed that at the end of less than two months four-fifths of the free oxygen had entered into chemical composition with the butter fat. At ordinary room temperatures the disappearance of the free oxygen was very rapid. That is, an oxidation of the elements of the butter fat had occurred, which not only impaired the flavor of the butter but also caused a destruction of the vitamins. With the loss of the vitamins

the food value is lowered, or perhaps disappears; there remains only the fuel value.

The moral is obvious. Foods require preservatives; otherwise they must be prepared in an atmosphere which contains no free oxygen. W. Paul Heath finds that an atmosphere of carbon dioxide is effective in preventing oxidation; it also imparts a pleasant flavor to butter.

In the manufacture of butter W. Paul Heath forces carbon in the churn at the bottom, thereby displacing the air at the top. With careful manipulation, practically all the free oxygen is expelled and the prepared butter is aerated with an atmosphere which not only prevents rancidity but preserves the vitamins as well.

The investigations of the Department of Agriculture leave no doubt about the value of a process which excludes free oxygen from the manipulation of food preservation. Experiments show that butter with a content of carbon dioxide instead of air will remain sweet for a long time—indefinitely, in fact.

Carbon dioxide is a pleasant stomachic stimulant and its consumption in aerated beverages is increasing. Indeed, humanity drinks millions and millions of gallons of aerated waters daily during the summer months, not for the sirups but for the refreshing effects of the carbon dioxide. It, therefore, should be as acceptable in butter and ice cream as in the so-called soda water.

Butter fat is by far the most important of the food fats, and its importance is due to its vitamin content. If the presence of carbon dioxide will preserve the vitamins, that fact alone is sufficient reason for its employment. At all events many dairies are giving the process a trial, and certainly it is worth trying.

Meteorological Laboratory.

Heathization is an important scientific advance in the making of butter, ice cream and bread. We will gladly mail you further information about this new day method of making better food products. Write to the address nearest to you.
